The experimental evidence, the detailed discussion of which will appear shortly, leaves little doubt that on such occasions, in the period before dawn, the ionisation in the Kennelly-Heaviside layer has been sufficiently reduced by recombination to permit of its penetration by waves of this frequency. Reflection, however, takes place at an upper layer which is richer in ionisation. With the advent of sumrise at a height of 100 km. or so, the Kennelly-Heaviside layer is formed again and deviation by the lower layer is suddenly established, the normal fall of the under boundary of the latter proceeding afterwards as the more direct solar influence increases the region ionised. As the day further proceeds, the experimental results suggest that another region of ionisation is formed below the Kennelly-Heaviside layer, which, while causing attenuation of the waves, does not very materially affect the height at which they are deviated.

The obvious bearing of these results on the nature of the solar radiation responsible for atmospheric ionisation and their correlation with the results of terrestrial magnetism must await a more detailed discussion. There is, however, one small point which may be mentioned here. It seems of interest in indicating the possibility that simultaneous observations between the same two stations on widely different wave-lengths might enable us to study the characteristics of both layers at the same time. Since ultrashort waves require a greater electron concentration to deflect them back than do the longer waves, there may not be enough electrons in the Kennelly-Heaviside

layer to send back the former, so that for angles of incidence less than a certain amount (e.g. in short distance transmission), such wave-lengths would be deviated by the upper layer at all times of the day The relatively large amplitude of the ray returned from the upper layer in the experiments mentioned above, in which 400 metre waves were used, demonstrates the low attenuation consequent on deviation at such great heights, so that with ultra-short waves the greater part of the absorption would probably take place in the penetration of the lower layer. Thus, even for transmission over long distances, we might expect a higher ray path, and deviation at the upper layer would result in less resultant absorption than a low ray path with deviation at the Kennelly-Heaviside layer It may be mentioned in this connexion that the American determinations of the height at which these ultra-short waves are 'reflected' fit in with the above ideas of their deviation at the upper layer

Dogsthorpe, Peterborough.

### Barrier Reefs of Tahiti and Moorea.

The surprising fact that fragments of volcanic lock occur in the barrier reef of Tahiti, as reported by Dr. Crossland in Nature for April 23, must be welcomed by all students of that remarkable structure, but that fact does not, it seems to me, prove the "original continuity of the present barrier reef from the [Island] shore to the ocean slope" outside the reef, as is stated in his second letter in the issue of July 2 The fact only permits the inference that the lagoon was formerly filled in some manner, perhaps by stream deltas instead of by a broadened fringing reef, so that island detritus could be transported to where the barrier now stands ference involves so extraordinary a series of changes from former lagoon filling to later lagoon excavation -for which there is no other satisfying evidence provided—that even the inference should not be accepted as valid until all other possible means of explaining the occurrence of the volcanic fragments have been excluded Further details as to the nature of the fragments and the manner of their occurrence are desirable

Dr. Crossland's rejection of the physiographic evidence for the subsidence of Tahiti, as provided by drowned-valley bays and as given in my account of the island (Annales de Géographie, 27, 241-284, 1918), seems to me of a piece with the neglect of such evidence on the part of Murray, Guppy, A. Agassiz, and other students of coral reefs, and that neglect was clearly the result of their unfamiliarity with physiographic evidence rather than of its weakness. Regarding the occurrence of embayed valleys, my observations in 1914 led me to be just as positive in asserting their presence near the isthmus which connects the two cones of the Tahiti doublet as Dr. Crossland is in asserting that "There are no bays in Tahiti." The bays to which I refer are "little bays which," as Dr. Crossland says, "open out of Port Phæton," and masmuch as they enter well back of the general shore line of the island between eroded slopes of volcanic rock, I took them to be the partly drowned valleys of ordinary streams, and so still regard them, in spite of their being described as "peculiar" by Dr. Crossland and as "certainly not drowned valleys." But I fully agree that Port Phæton Bay is merely a re-entrant space between the two confluent volcanoes of which Tahiti is composed. This origin was by no means overlooked in my article, for I there said that Port Phæton Bay on the southwest side of the inter-cone isthmus and the corresponding Taravao Bay on the north-east side of it

"sont évidemment en rapport avec la forme mitiale des deux cônes contigus" (p. 245)
When the small bays which open out of Port Phæton were produced by the entrance of sea water into their little valleys in consequence of a moderate subsidence of the island, all the many larger valleys of the island were presumably embayed also, but they have all been filled with alluvium, because the drainage areas tributary to them are larger and more The small bays, which still remain mountainous but partly filled, appear to have escaped complete filling because they receive streams from small drainage areas. Of course the many bay-filling deltas have a seaward slope. Indeed, the associated facts that the delta flats are in no case level and that their streams have a rapid flow along them, both of which Dr Crossland mentions as if to discredit the origin of the flats as the fillings of former bays, have no such bearing

On the other hand, a number of the delta flats are a quarter or half mile wide at their mouths; and that so great a width should there be given them by the lateral erosion of their streams, while the streams still flow in sharp-cut V-valleys upstream from the flats, seems to me unreasonable. The more reasonable explanation of the flats is, as above stated, that they are the fillings of valleys that were embayed by island subsidence; and this explanation is all the more reasonable in view of the absence of a shallow rock platform in front of the great cliffs in which the inter-valley spurs have been cut back by former wave action around most of the island circumference

I am glad that Dr Crossland has recognised these old manne cliffs, for they have generally been overlooked by earlier observers, excepting Agassiz: indeed, at least two observers have explicitly stated that there are no sea cliffs at the base of the island slopes Surely, a rock platform must have slanted gently seaward just below sea-level when the cliffs were cut back by the ocean waves during a reefless period in the earlier history of the island; the absence of reefs at that time being presumably due to the abundant outwash of detritus from the nonsubmerged valley mouths, as is to-day the case in the reefless island of Reunion. But instead of being now fronted by such a platform, the cliffs of Tahiti are fronted by a lagoon twenty or more fathoms in depth, even though the lagoon floor has been aggraded by an unknown measure of detrital deposits derived from the island and the reef. Evidently, therefore, the cliff-base platform has subsided to a greater depth than that at which it was originally cut, and this subsidence must have been the same as that which produced the now delta-filled valley embayments. The cliffs as at present seen must plunge below sea-level

As to my interpretation of the slopes of white sand inside of the Tahiti barrier reef as evidence of inwash from the reef, and as therefore contradicting the idea that the lagoon is now suffering excavation, I am by no means persuaded that it is erroneous. Agassiz' account of his dredgings in the lagoon lead to the same conclusion, for its floor contains much detritus from the island. If other parts of the inner slope of the barrier reef than those which I saw are devoid of inwashed sand, that may perhaps be because the reef is there broader, or because the sand has been shifted by lagoon waves down the slope from the reef to the middle depths of the lagoon floor. But regarding this point, as well as the blocks of coral rock on the sand slopes, I will wait for the appearance of Dr Crossland's fuller report, which I will examine with the same interest that I hope he

will give to my book on "The Coral Reef Problem," shortly to be published by the American Geographical Society of New York. He will there find many details concerning my observations on numerous Pacific reefs, the present lack of which he is good enough to regret In the meantime I may reter him to a rather lengthy article on the coast and reefs of New Caledonia in the Annales de Géographie for 1925, and also to a small book on the Lesser Antilles, with particular regard to their imperfect barrier reefs, published by the American Geographical Society in 1925 But the details that I give are chiefly physiographical rather than biological That side of the problem I am not prepared to deal with; and in any case it seems to me the less significant side, so far as reef origins are concerned, for it is to the forms and the changes of the island coasts, as determined by abrasion, erosion, and movements of upheaval or subsidence, that the reef-builders must adapt themselves.

Dr. Crossland is fully warranted in saying, so far as my published articles show, that I seem "to have missed the cliffs ' on the north side of Moorea, a smaller island than Tahiti, not far north-west from it, for in my Tahiti article it is unfortunately asserted that "aucune falaise n'entaille les contreforts" of the smaller island (p. 277). Nevertheless I saw and sketched the north-coast cliffs of Moorea, as will appear in my forthcoming book, and I have even ventured to explain their local occurrence as the consequence of a prolonged attack by the sea on the north coast after the subsidence of the island had begun, because the two largest valleys of Moorea open on that side, and the abundant detritus that they have discharged must have drifted westward from the valley mouths and formed a beach along the shore, thus preventing reef growth and permitting continued cliff cutting there, although, in consequence of sub-sidence, reefs had then already been formed by upgrowth around the rest of the shore line and protected it from abrasion It is because of this subsidence that the lower cliffs, which were presumably cut all around the island in its unprotected youth, are no longer visible. Cliffs are seen to-day only on the north side where, as above suggested, the continuation of abrasion after subsidence had begun gave the cliffs a greater height than elsewhere This explanation is rather venturesome, but it is better than none.

In view of my failure to mention the north-coast cliffs of Moorea, Dr. Crossland concludes that my "criticism of Daly's theory of glacial control . . . fails in this case." By no means: but I must leave that long story for more deliberate presentation elsewhere. Suffice it to say now that the absence of cliffs from most of Moorea and from many other reefencircled islands in the true coral seas of the Pacific not only contradicts the glacial-control theory, but also goes far toward proving that the partly sub-merged cliffs of Tahiti were not cut back by low-level abrasion in the glacial period. It is only in the marginal belts of the coral seas that cliffs due to lowlevel abrasion are to be found, as I have shown in the above-cited booklet on the Lesser Antilles and elsewhere. In conclusion, let me add that I accept Dr. Crossland's dictum that "barrier reefs can no longer be taken as an index of subsidence without independent proof from the adjacent land;" and it is precisely because such independent proof is almost universally forthcoming that the upgrowth of barrier reefs as a consequence of island subsidence may be generally accepted, essentially as Darwin long ago W. M. DAVIS. inferred.

### Surface Layers on Tungsten produced by Active Nitrogen.

WE have found that a fine tungsten filament at a very dull-red temperature placed in a stream of nitiogen undergoes a considerable (10-25 per cent ) lowering of its resistance (for constant current flowing through it) when active nitrogen produced up-stream At the by a condensed discharge passes over it same time the colour changes to a much duller red, that is, the radiation is decreased. These changes persist until the filament is momentarily flashed at a white heat, whereupon the original condition is regained. Apparently a surface layer of some soit forms on the filament and produces a lowering of its temperature. The resistance of the filament at 100m temperature is the same either with or without the

The same cooling effect can be produced by bombarding still nitrogen with electrons from another source filament accelerated by suitable electric fields. In a tube with large nickel electrodes which had been thoroughly degassed by the repeated use of an induction furnace, this effect was first detectable when the exciting electrons had an energy of 11 volts. The rate of formation of the layer increased rapidly with the voltage. In a second tube, in which the anode was a hot tungsten spiral, the effect was not detectable below 22 volts. The effect was independent of the potential of the testing filament, showing it to be produced by a neutral substance. It seems possible that in the first case the active substance was produced at the low voltage by bombardment of the metal surfaces. These effects were obtained both with commercial nitrogen which had been passed over hot copper and with nitrogen prepared by Waran's method which was so pure that it would not give the afterglow.

Peculiar current-voltage characteristics were obtained with the tube having the hot anode. With increasing voltage the current increased, as in other gases, up to 22 volts, at which voltage it began to fall off At 25 volts an arc struck, the current took a sudden rise immediately, followed by a decrease in two or three seconds to a value considerably below that which it had had before the arc struck. Further mcreases in voltage produced slight increases in current. Upon decreasing the voltage, the current dropped off until the arc broke at about 20 volts. Here there was a sudden decrease in current followed by a slower rise to a much higher current, the same as that at the corresponding voltage before the arc had struck. The two currents were the same for lower voltages. That these effects are characteristic of nitrogen and not ascribable to charges on the walls of the tube seems probable, for no such effects were observed with argon in the tube. A decrease of the thermionic current in nitrogen at much lower pressures and lugher voltages was observed by Langmuir (Phys. Rev., 2, p. 450; 1913). We also observed a considerable temporary decrease in the thermionic emission from a tungsten filament as ordinary active nitrogen passed over it.

A tube was constructed having a pile of tungsten foil discs, spaced apart, and mounted so that they could be flashed with the induction furnace. Electrodes and filaments were provided, so that the nitrogen could be activated either by the disruptive discharge or by electron bombardment of known voltage. Gas pressures were measured with a hot wire guage of small volume. The total volume of the tube and gauge was small enough in relation to the area of tungsten that a gas layer one atom deep on the latter, if evaporated, would cause a pressure of the order of 0·1 mm. The tube was baked out under

exhaust, as usual, at 450° C and the discs well degassed by flashing With a few tenths of a millimetre of nitrogen in the tube, and keeping the discs at a dull-red heat while the spark discharge was passed, a partial clean-up of the gas was obtained exhausting the remaining gas and closing off the pump, the discs were flashed, with the discovery of a considerable quantity of gas Gas so recovered was not cleaned up by a hot tungsten filament, and on examination with a hand spectroscope gave all evidences of being nitrogen The experiment was repeated a large number of times, varying the time of the spark discharge. In all cases except where the time of discharge had been very short, the amount of gas recovered on flashing was a constant quantity, approximately that to be expected from a layer one atom deep Exactly the same results were obtained by activating the nitiogen with an arc at 25 volts At 15 volts there was no indication of clean up, or of a gas layer on the tungsten which could be removed by flashing

Our conclusions are that a clean tungsten surface at a dull-red heat, if placed in an atmosphere of nitrogen, activated either by a condensed discharge or by an electron bombardment at more than 22 volts, becomes covered with a nitrogen layer of the order of one atom The effect of this layer, at this comparatively low temperature, is to cool the surface. It seems probable that it does this by allowing the surface to conduct more heat to the gas, ie by increasing the accommodation coefficient. At relatively high temperatures, the same layer is probably so unstable that only a small fraction of the surface can be covered at any one time, but it acts to increase the work function The flashing of a filament covered with such a layer in the neighbourhood of a clean filament causes the production of a layer upon the latter Apparently the layer evaporated by flashing comes off in an active form. These experiments suggest that active nitrogen can be produced by bombard-inent of nitrogen gas with 22 volt electrons, but further work is necessary to establish this conclusion. The experiments are being extended and completed, and will be described in detail later.

### The Temperature Variation of the Elasticity of Rochelle Salt.

Valasek ( $Phys.\ Rer$ , 478, 1922) has studied the temperature variation of the piezo-electric modulus of Rochelle salt. He tound abrupt change m the values of this modulus at temperatures of -15°C. and 23°C. using crystal slabs with their length at  $45^{\circ}$  with the  $\bar{b}$  and c crystallographic axes In a later paper he describes experiments undertaken to investigate the temperature variation of other physical properties of the crystal, but these experiments do not indicate discontinuities such as occurred in the case of the piezo-modulus

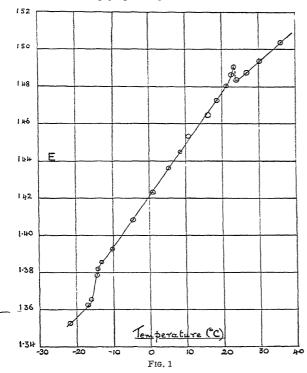

The object of this note is to point out that there is evidence for the existence of similar discontinuities in the values of the elastic constants of this crystal at

these two temperatures

Slabs of Rochelle salt have been cut and mounted so as to form piezo-resonators, similar to the quartz piezo-resonators used in modern wireless practice As shown by Cady and by Dye, these piezo-resonators possess a well-defined resonant frequency, which depends on the dimensions, the density, and the Young's modulus of the crystal. Hence, by investigation of the resonant frequency at different temperatures, it is possible to deduce the temperature variation of Young's modulus for the crystal

Such an investigation has recently been carried out in this laboratory, using a method due to Cady (Proc. Inst. Radio Engrs.. 10, 83; 1922). By using a calibrated wavemeter of the resonant circuit type, resonant frequencies could be determined to within less than 1 part in 5000

The following graph (Fig. 1) shows the variation of

the extension modulus in a direction at 45° to the b and c crystallographic axes, between -23°C, and 36° C. The ordinates represent a quantity, E, which is proportional to the extension modulus; the extension modulus is the reciprocal of Young's modulus. It will be seen that there are two distinct breaks in the curve, one in the neighbourhood of - 15°C and the other in the neighbourhood of 23°C. Similar results have been obtained with crystals cut in other directions.

A full account of these experiments is in course of preparation and will be published elsewhere shortly. R. Morgan Davies.

### Newtonian Time Essential to Astromony: A Correction.

In the supplement to NATURE of April 9, I was permitted to discourse on the necessity, after Newton, of a universal time for astronomical science, and had identified it objectively and everywhere with the intrinsic vibrational times of the material atoms. In the last section it was imagined that this course had eliminated what had been considered to be a formidable discrepancy in the verification of the relativity scheme for gravitation.

It is now to be confessed without further delay that this is not so. The reason is, briefly, that it is

only the changes of time-epoch in the observer's own frame that can be neglected, which makes dT/dtequal to  $e^{-1}$  instead of  $e^{1}$ . This change conforms with the discussions, when duly amended, of variable electric mertia, and of the influences of gravitation on the paths of rays and on the spectrum But it seems to make hav of any gravitational Action function of the type naturally assumed, namely,  $\Sigma |_{m_s} cds_s$  with adoption of the usual form for  $ds^2$ , and also equally of the Einstein postulate that each orbit is separately a geodesic on its own account

It appears that one has to conclude that another invariant form must be found for the Action function, or else if that be not feasible, that this type of relativity scheme stands in essential contradiction with the spectro-copic postulate of absolute time for the atoms, as measured in their own frames, and unaffected by accelerations of their motions.

Portrush, Aug. 18.

### On the Structure of the Spectra of Krypton and Xenon.

As absorption measurements proved to be the key to a complete analysis of the arc spectra of neon and argon, we recently extended the use of the method to include an investigation of the spectra of krypton and

As in the case of neon and argon, we found that some lines in the spectrum of krypton were powerfully absorbed by this same gas when a weak electrical discharge was passed through it With xenon similarly stimulated, selective absorption of spectral lines was also observed Even a casual glance at photographic spectrum plates obtained with both gases showed this weakening of selected lines. As was to be expected, lines in the visible spectral region were scarcely, if at all, absorbed.

Examples of spectral lines, showing strong absorption by the method indicated, are, in the case of krypton,  $\lambda\lambda7601$ . 7854, 8104, 8112, and in the case of xenon,  $\lambda\lambda8231$ . 8819. The degree of absorption that took place in the case of other spectral lines is being determined from microphotometric observations.

In our analysis of the spectrum of xenon, the wavenumber difference 9140 was observed between pairs of wave-lengths with the following frequencies

| 11167, | 11977, | 12675, | 13655, | 13664, | 15371, | 20307, | 21117, | 21815, | 22795, | 22804, | 24511, 116177, 116181, 117552. (25317, (25321, (26692.

The wave-number difference 9140 is the same as that between the wave numbers of the resonance lines λλ1469 9 and 1295 8 found by Hertz. The pairs of lines are therefore  $S_2p_i$  and  $S_1p_i$  (i=1 to 10) lines expressed in the old notation originally used with The infra red wave-lengths  $S_3p_1$  and  $S_5p_1$ involve a metastable state, but wave-lengths showing strong absorption are found among them.

The results given above go to show that the structure of the spectra of the heavier rare gases krypton and xenon corresponds to that of the spectra of the lighter ones neon and argon, namely, a  $S_0$  normal state, a  ${}^3P_{012}$  state comprising 2 metastable sub-levels, a  $P_1$  state, etc. There is, of course, a much larger separation between the  ${}^{3}P_{012}$  and  ${}^{\prime}P_{1}$  levels with krypton and with xenon than with either argon or neon.

# Canadian Hydro-Electric Power Development.

By Dr. Brysson Cunningham.

II

IN a review of last year's activities in water-power development by provinces, Quebec took a pronounced lead with 168,000 h p, followed by British Columbia with 48,000 h p, Manitoba with 43,200 h.p.. Ontario with 5700 h.p.; New Brunswick with 2600 h p, and Nova Scotia with a small amount. Dealing first with Quebec, it is to be

the river of that name, flowing into the Ottawa River, is associated with the Canadian International Paper Company, which has pulp and paper mills in the district, while a large quantity of power will be diverted to the Niagara system of the Ontario Hydro-Electric Power Commission.

The writer did not have an opportunity of inspecting the power stations in this district, but

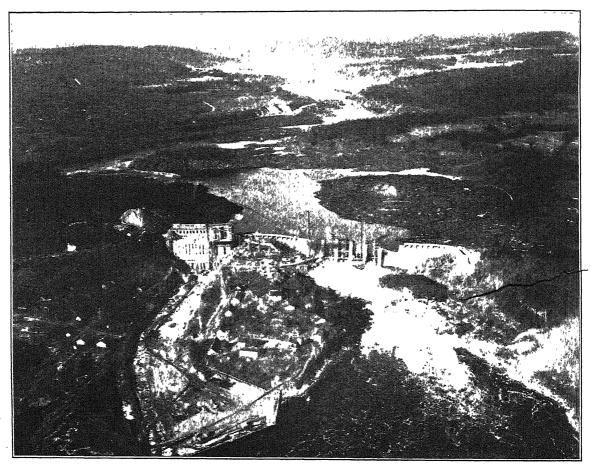

Fig. 2.—Chelsea Falls development of the Gatineau Power Company, Gatineau River, Quebec. Capacity, 170,000 H.P. Under construction, 1926. This plant has recently been completed Reproduced by permission of the High Commissioner for Canada in London

noted that though the plant actually placed in operation during 1926 fell short of the record year of 1925, projects now in course of construction represent a future addition of more than 1,400,000 h.p., which indicates a continuance of substantial progress. The outstanding event of the year was undoubtedly the virtual completion by the Gatineau Power Company of two installations on the Gatineau River at Chelsea and Farmers' Rapids and the initiation of constructional operations at Paugan Falls, the three sites having a total estimated capacity of 530,000 h.p. The Gatineau Power Company, which operates in the valley of

No. 3018, Vol. 120]

he had the privilege of going through the two power stations of the Shawinigan Water and Power Co. at Shawinigan Falls in the St. Maurice River Valley, a group of the most important hydroelectric installations in the province, and he can testify with appreciation to the very complete and efficient service of generating and distributing plant which he found in operation. Since its incorporation in 1898, the Shawinigan Water and Power Co. has grown to be the fourth largest distributor of electricity in the world: it controls in the form of electricity or hydraulic supply nearly 600,000 h.p. The St. Maurice River is one of the largest rivers in the whole of Canada. It has its

source at the divide between the valley of the St. Lawrence and the watershed of Hudson Bay at a point about 300 miles north of the former river, and it drains a region of nearly 20,000 square miles Practically the whole drainage region is forest or

woodland, a circumstance which is most favourable for maintaining constancy of river flow. In a part of its course, the waters of the river descend more than 250 ft. within a distance of a dozen miles, and it is here that the principal power stations have been developed.

Shawingan Falls was the site of the first development, and it is now the centre of the Company's generating and transmission system. Located about twenty miles from the junction with the St Lawrence, the curvature of the St. Maurice at this point, where the fall is 150 ft., lends itself admirably to economical exploitation. The first installation, completed in 1902, consisted of two 5000 h p. water wheels and generators, now incorporated in Power House No.

1, the capacity of which was raised in 1910 to 58,500 h.p. by the addition of four units of 11,500 h.p. Power House No. 2, begun in 1911, with two 20,000 h.p. units, received a third unit in 1912; two additional units in 1914, and a sixth unit of 45,000

Canada, Ltd., and 15,000 h p. to the Belgo-Canadian Paper Company in the form of hydraulic power.

At Grandmère, which is six miles above Shawinigan, the power development of the Laurentide Power Company, Ltd., an allied concern, comprises

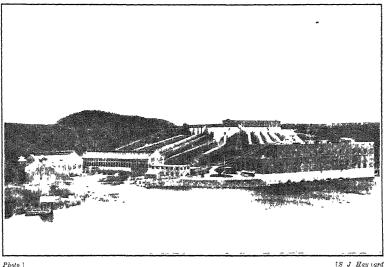

Fig. 3—Snawingan Power Station. Capacity, 145,000 H P

Reproduced by permission of the Shawingan Water and Power Company.

six 20,000 h.p. units and two 22,000 h.p. units, with provision for a final unit of 22,000 h.p. to be installed in the future. The total capacity at present is 164,000 h.p.

The latest addition to the Company's generating

system is an installation of 120,000 h.p. at La Gabelle, seven miles below Shawinigan. This was completed and put into operation in 1924. Provision has been made for the addition of another unit of 30,000 h.p.

In the short stretch of about a dozen miles of river between La Gabelle and Grandmère, there are, therefore, three hydro-electric generating stations having a total capacity of 507,500 h.p. The local storage ponds of the three stations are under unified control and a balance is maintained of the electrical loads so that the water is utilised to its full extent in passing down the river.

Through a subsidiary company (the North Shore Power Company) the Shawinigan Water and Power Company completed and put into operation last year

another installation of 22,000 h.p. at St. Narcisse on the Batiscan River (about 20 miles below the St. Maurice River), replacing an installation of 1600 h.p., reputed to be the first in the British Empire to supply energy over long-distance transmission.

The question of transmission is, of course, an

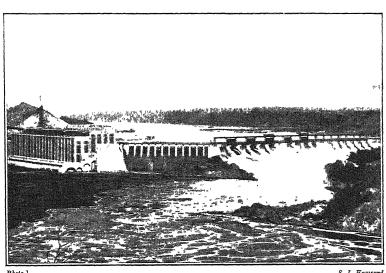

Fig. 4—Grandmère Power Station. Capacity, 164,000 H P.

Reproduced by permission of the Shawinigan Water and Power Company.

h.p. in 1923; thus bringing the total capacity up to 145,000 h p. at the present time. There is contemplated the installation of two more units of 45,000 h.p. each; so that, when completed, the total electrical capacity of Power Houses Nos. 1 and 2 will be 293,500 h.p. In addition, 50,000 h.p. is supplied to the Aluminium Company of

No. 3018, Vol. 1201

important problem in dealing with the supply of energy from the generating centres to the various localities of consumption. The Shawmigan Company transmits 3-phase alternating current at 114,000 volts over four lines to Montreal, and the high tension used, together with the large amount of current passed, necessitate very careful insulation. Aluminium is largely taking the place of copper for the cables of transmission lines, and this step is opening out an important industry in the production of aluminium from bauxite. The

300 miles of steel tower and steel pole voltage lines and about 400 miles of high voltage wood pole lines, with more than a thousand miles of wood pole lines of low voltage. The lines on the southern route to Victoriaville cross the St Lawrence River one mile above the city of Three Rivers, by means of an overhead crossing which is one of the largest in existence, both as regards length of span and height of tower. The distance between the two towers is 4800 ft, which, with the anchorage spans on each bank, gives a total length of 6324 ft of

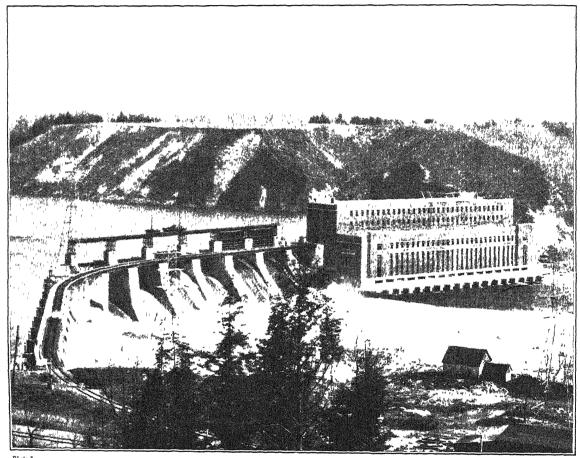

Photo ?

FIG. 5 —La Gabelle Power Station Capacity, 120,000 H P Reproduced by perimission of the Shawingan Water and Power Company.

[S J. Hayward.

process is being developed among other places on the Saguenay River, where the bauxite is imported from districts in Central and South America, to be treated with the aid of the local hydraulic power.

The high voltage transmission lines forming the trunk lines of the Shawinigan system radiate from Shawinigan Falls westward to Montreal (85 miles), eastward to Quebec (55 miles), and southward across the St. Lawrence River to Sherbrooke and the Thetford Mines Asbestos district Three general types of support are in vogue: steel towers, steel poles, and wood poles. Of these, the steel structures are the more permanent. There are

crossing. The towers stand 375 ft. above the foundation level. The minimum clearance above the water is 165 ft, so as to admit of the passage of ocean liners between Montreal and Quebec.

It would be possible to dwell at considerable length on the development of water power in the Province of Quebec alone. In addition to the Gatineau River, the St. Maurice River, and the Saguenay River installations, to which reference has been made, there are a number of minor installations of cumulative importance, some of which in time will form the nuclei of future groups of power centres Projects which are in hand, or under active consideration, include a 65,000 h.p.

development on the Prairie River, near Montreal, by The Montreal Island Power Co a 50 000 h p development at Spicer Fall on the St François River, by the Southern Canada Power Co 40,000 h p plant at Mountain Fall, on the Rouge River, by the Canadian International Paper Co a 50,000 h p addition to the Ottawa River Power Company's installation at Bryson, and a number of lesser calibre.

The Quebec Streams Commission continues a very useful and beneficial work in fostering waterpower development in the Province. The Commission has extensive storage reservoirs established on the St Maurice and St François Rivers Kenogami Lake Ste Anne de Beaupré and Mitis Rivers, all of which are at present reported as filled to capacity, the various plants in connexion therewith being thus assured of an ample supply of water during the winter season. The Commission now has under its supervision the construction of the Baskatong reservoir on the Gatmeau River, which is at the point of completion. This reservoir is formed in part by Baskatong Lake, and has a capacity of 94 billion cubic feet, it serves to regulate the flow to 8000 cubic feet per second Other work of the Commission includes surveys and investigations of likely projects, some of which will materialise in due course.

The Province of Ontario includes, of course, the world-renowned Falls of Niagara, or, at any rate, the Canadian portion of them The Ontario Hydro-Electric Power Commission recently completed two large stations, the Queenston on the Niagar River with 550,000 hp development, and the Cameron Falls on the Nipigon River with 75,000 h p development The Queenston Station is now fully loaded, and for the further supply of the Niagara system the Commission has entered into a contract with the Gatineau Power Company for the delivery of from 230,000 to 260,000 h p over a 220,000 volt line, commencing next year

In Northern Ontario, the Abitibi Power and Paper Co has completed the transmission line from its 48,000 hp. plant at Island Falls to the mills at Iroquois Falls. The town of Cochrane is also served from this line A short distance to the west, the Spruce Falls Co. has in hand the

construction of works at Smoky Falls on the Mattagann River which will result in the obtainment of 70,000 hp, which will be utilised to supply energy to the Company's pulp and paper mills in the district

In the extreme west of the Province, a 17 000 h p. development at the western outlet of the Lake of the Woods has been achieved by the Keewatia Power Co In the same district the Bachus Brooks Co has undertaken the construction of three power sites on the Seine River, which will have an aggregate capacity of 37,620 h.p. It is expected that all three will be completed and in use by the end of the current year

Important developments are in progress in British Columbia and Manitoba, but as these are much farther afield than the writer's ambit, only very brief allusion will be made to them tormer Province there are works in hand on the Kootenav and Powell Rivers while the British Columbia Electric Railway Company's dam at the Alouette lakes, eight miles north of the Fraser River and about 25 miles due east of Vancouver, has proved a valuable addition to the supply at Stave Falls A project promoted by the same Company at Bridge River is designed for an initial capacity of 54,000 h p . which may ultimately reach a total of from 550,000 to 700 000 hp. In Manitoba, the City of Winnipeg and the Manitoba Power Company have made notable additions to their respective installations

There is not, however, quite the same inducement in the Western Provinces of Canada to exploit water-power as in the Provinces of Quebec and Ontario Coal is procurable, and although not of high quality, yet the power situation is not so compulsory or so drastic as if no alternative source were available It is therefore in the Eastern Provinces, with their conspicuous lack of coalmines, that the greatest and most sustained effort is being made to develop water-power, and the foregoing notice of the steps which are being taken to remedy a striking deficiency in the natural fuel resources of the country, so obviously prejudicial to the development of its industry and commerce, can scarcely fail to interest those whose duty it is to survey the field of Nature and exploit it in the interest and service of mankind.

### The British Association at Leeds.

IN the phraseology of our trans-Atlantic cousins, the Handbook for the Leeds meeting may have 'said a mouthful' when it describes the area visited this year by the British Association as a 'conurbation,' but behind the word a very important feature of this year's meeting is struggling, if clumsily, for recognition. Proximity of population, and the interlacing of road and rail communication, make the area of the West Riding of Yorkshire one urban unit with a population between one and a quarter and one and a half millions. At the same time, local civic spirit proclaims its divisibility into independent units every whit as

strenuously as the physicist splits up the chemist's The unmitated visitor must not confound Dewsbury with Batley, or (as the provisional issue of the time-table did !) Halifax with Huddersfield; his crime is as great as that of the visitor to the Western States who assumes that Los Angeles and San Francisco are much the same thing

The Englishman may pay about the same high price for grape fruits from California and Florida, but this is a mistake condemned on entirely different grounds, and equally emphatically, by both these States; similarly, local championship individualises the products of the local looms, and in its own

way has nothing to learn from the Florida story of the turtle masquerading in the Californian visitor's blankets as a bed bug, to demonstrate the scale of things in Florida These civic rivalries kev up the pace of life in the West Riding, both in industry and in sport Local league cricket is in a different world from the country cricket of the west of England, and the Whitsuntide rival counties of the White and the Red Rose are credibly reported on that occasion to say "How do on their first morning, afterwards nothing but How's that!"

In such an area, visits to works and to educational and civic institutions by interested Sections, can be almost indefinitely continued, each city or borough having its own lesson to teach Similarly, the Association's meeting is characterised by a very large extension of the list of citizens and childrens lectures, an experiment which will be watched with interest. These lectures are still somewhat a new development, and there is sometimes a difficulty in utilising the favourable opportunity to attract a general audience to listen to science which is created by the general publicity associated with the meeting.

The Handbook has a very interesting chapter by the editor. Dr. C. B Fawcett, upon the location of Leeds, which began as a foothill town on the eastern edge of the Pennines. Its central position, halfway between the south coast and the Highlands, between London and Glasgow, and between North and Irish Seas is naturally emphasised Leeds citizens at present consider themselves centrally placed also for the dissolution of the series of

from the Atlantic and apparently disperse in rain down the flanks of the Pennines. At the same time, from the north of Scotland, from Ireland and the Isle of Man, and from the Riviera, holiday makers return with tales of days spent in sunshine

August has had an exceptionally heavy ramfall record, and the visitors when in the gardens of their hosts are asked to remember that for most days of the last month it has been quite impossible to work upon the sodden land have of necessity been altered. Section K (Botany) which always enjoys splashing about a swamp, as it did with success both at Southampton and in Canada, had arranged to visit the interesting marsh at Askham, near York, referred to by Mr Sledge in his botanical notes in the Handbook This marsh was quite maccessible a few days before the meeting, and the Yorkshire papers still record flood conditions in various parts of the three Ridings that are quite remarkable for the season This year the adventurous visitor to Gaping Ghyll should certainly find the 340-foot waterfall descending this pothole an impressive if damp experience

The maugural meeting was held in the Majestic Cinema, which possesses a very large auditorium. The overhead lighting was strengthened specially for the occasion, so that the audience should both

be able to see and be seen

On Tuesday, Sept 6, the R W Provincial Grand Master of West Yorkshire, the Viscount Lascelles, K G, will attend a meeting at the Masonic Hall, Great George Street, to welcome visiting members who are Freemasons HRH Princess Mary will \_ also attend the Civic Reception to be held at the depressions which follow in melancholy succession | City Art Galleries on Thursday night, Sept 1.

# The Stone Age in Kenya.

THE brief reports which have reached England from time to time of the discoveries relating to the stone age in Kenya by Mr. L S B. Leakey (see NATURE, July 16, p. 85) have pointed to the possibility that evidence of great importance for the early history of man in this part of Africa might be brought to light at any moment. The announcement, therefore, that a preliminary report on the excavations recently carried out by Mr. Leakey and Mr. B. H. Newsam, with the advice and co-operation on geological points of Dr. Nilsson and Mr. E. J. Wayland of Uganda, would be presented to Section H (Anthropology) at the meeting of the British Association at Leeds had been received with considerable interest. In the absence of the authors, who will return to England later in September, the report was communicated to the Section by Dr. A. C. Haddon

The work covered by the report is in the nature of a preliminary survey and deals with the results of excavations in two areas, one in the neighbourhood of Lake Nakuru on the floor of the Rift Valley, the second at Upper Elmenterta.

Before dealing with the present discoveries, it may be recalled that ever since 1893, implements and obsidian flakes, some accompanied by pottery, have been found in Kenya Some of these were surface finds, others were situated at a depth of two to three feet Some, again, were obtained from the high level beaches of the Rift Valley Among them also were implements comparable to the palæolithic implements of Europe, and in some cases they were associated with the remains of extinct animals. Similar finds have been made in Uganda, and Mr. Wayland has classified these implements into three divisions. Reference may also be made to the skeleton found in the Oldeway Gorge in 1914 which was associated with fauna now extinct.

Turning now to the results of Mr. Leakey's first year's work on the Nakuru site, evidence was found for at least two periods of high lake-level reaching to 6604 ft. above sea-level as against the present 5768 ft. In relation with these high levels there was evidence for falls to a point below the 200-ft. level It is suggested that these high levels represent pluvial periods to be correlated with the glacial epochs of Europe This suggestion awaits further examination in the light of evidence to be furnished by fossil bones and shells collected from the various horizons in the lake deposits.

The archæological site at Nakuru is situated

365 ft above present lake-level and consists of a The two upper deposit along the edge of a cliff strata show no sign of a submergence and therefore must be later than the high lake-level In these upper strata, ten burials were found distributed through a depth of 13 ft With them were large numbers of implements and pottery fragments as well as stone bowls, the latter being more numerous in the upper levels. One skeleton was found in perfect condition and alone afforded material for detailed measurement. The notable characteristics were the length and width of the face and the great depth of the mandible at the symphysis, the height of the palate and the prominent nose with a low index of 50. The skull is markedly dolichocephalic The associated industry is essentially microlithic Beneath these two strata and obviously earlier in date, was a small deposit of sand and pebbles which had been subject to the action of water This contained a few obsidian flakes, the tools being for the most part backed blades

At Upper Elmenteita two sites were investigated The first is at a height of 393 ft above present lakelevel, and is situated on the edge of a cliff which consists of lava overlying an alluvial deposit The cliff is one side of a valley which was cut by a prehistoric river during an interpluvial period, and afterwards filled by a rise of the lake, most of the later alluvium being washed away in a subsequent In this later alluvium, which lay in pockets in recesses and crevices, were found the remains of twenty-six individuals scattered about at various depths with obsidian tools, pottery, stone mortars. and eggshell beads. It is suggested that these individuals belong to a period previous to that at which they were deposited where they were found All the bones are more or less fossilised and well preserved There are at least two skull types Elmenteita A is a primitive type Remarkable features in the mandible are the depth at the symphysis—11 mm—the thickness of the horizontal ramus and the relative height of the ascending ramus. The angle is also remarkably obtuse Other notable features of this type are the low forehead, the length and breadth of the face, and the exceptionally long and narrow nose, of which the index is 47.4 The skull is dolichocephalic, its index being 68.2 The second type, Elmenteita B, is not so primitive as Skull A, differing from it tools.

m its greater breadth, the index being 75. It has a remarkably high cranial capacity-1660 96and an exceptionally narrow nose with an index Neither of these types resembles the modern negro of the country

A cave or rock-shelter at Elmenteita, situated at a height of 594 ft above present lake-level, produced important stratigraphical evidence. Eleven horizons were exposed, of which the first three were modern and showed no tools, the fourth was alluvial, and the fifth composed of

debris from the roof The sixth produced implements and pottery, the eighth was alluvial, and the ninth rock rubble, while the tenth was an occupation hearth layer with obsidian tools and The eleventh contained burnals. If, as is argued, the alluvial deposits at four and eight are to be identified with the high lake-levels, the first or later prehistoric period belongs to the second interpluvial and the lower or earlier culture to the first interpluvial Of the two cultural horizons, the first or later belongs to the neolithic in culture if not in date and is to be compared to the Elmenterta site (Monro's Faria), while the earlier contains a much cruder industry without pottery, the implements being rough flakes showing just a very small trace of secondary chipping In the lowest level, 14 ft below the surface, have been found traces of burnals, but at the time the report was written no human remains had been taken out

The most conclusive evidence as to the age of the industry with lunate and backed blades was found in a drift across the Enteril River, giving a clear section across the alluvial plain at a level of 330 ft above present lake-level and showing very clearly the deposits during the high-level periods In the deposits of the last pluvial period are a number of obidian tools, chiefly lunates and backed points, definitely associated with fossil bones which would seem to belong to some form of hippopotamus

Taking the results of the investigation as a whole, they would go to show the occurrence of two high lake levels indicating two pluvial periods, the existence of stone age cultures earlier than both the high lake-level deposits, and in the case of the earliest deposits antedating the earlier rise of the lake, human remains are associated with crude

# Obituary.

SIR HARRY JOHNSTON, G.C.M.G, K.C.B.

THE death of Sir Harry Johnston removes one to whom the British Empire and science owe Henry Hamilton Johnston was born great debts at Kennington on June 12, 1858, and he died near Worksop on July 31 last at sixty-nine years of age He was educated at the Stockwell Grammar School, King's College, London, and later at the Royal Academy Schools. Endowed with great natural ability and with a vigorous and fearless mind, he soon displayed an amazing versatility which led him to success along many different paths. Distinguished as an artist in water colours, an intrepid explorer, a naturalist, an anthropologist, a linguist, and a writer, he won for himself a permanent place in history as one of the builders of Great Britain's African Empire and as a wise colonial administrator Political activities, alone or in conjunction with Cecil Rhodes, Sir Alfred Sharpe and others, constituted the most important part of Sir Harry Johnston's life-work An excellent account of these activities was published in the Times for Aug 1.

Although he had visited Tunisia previously, Sir Harry Johnston's connexion with Africa may be said to date really from 1882, when he accom-

panied Lord Mayo on a journey through southern Angola. Thence he marched away northwards by himself to meet Stanley on the Congo. journey and his book ("The River Congo") describing it displayed the power and resource of the young explorer. As a result he was chosen to lead the scientific expedition to Kilimanjaro organised by the British Association and the Royal Society. Politics, science, and art marched with Johnston on this, as on all later occasions; the fruits of the expedition were important biological collections, a valuable book ("The Kilimanjaro Expedition"), and a crop of satisfactory treaties with the native chiefs In 1885, as vice-consul in Cameroon and the Niger Delta, Johnston showed his capacity for courageous Later came special missions to, administration or long spells of administration in Nyasaland, what is now called Northern Rhodesia, British East Africa, Uganda, and Liberia, where his labours in Africa terminated in 1906.

In spite of all difficulty and danger, and of the pressure of onerous duties, Sir Harry Johnston never lost his early enthusiasm for Nature and art. No administrator in Africa or elsewhere has ever done so much as he did to advance science in the countries under his control. His own contributions to science were many, his explorations of Kilimanjaro, Ruwenzori, and the Semliki Forest, the discovery of the okapi, anthropological investigations among the pygmics and other African people, and studies of the native languages being among the most important. Firm in the belief that white rule in Africa depends ultimately upon a complete knowledge of the country, its natural history, its people and their institutions, Johnston lost no opportunity to collect information and material himself, and what was still more important, he urged all his subordinates to the performance of a similar duty. He was too wise to fritter away his time in a vain attempt to work out everything for himself. On one occasion one of his lieutenants was heard to grumble. "I collect endless mammals and birds," he said, "but Sir Harry won't look at them. All he says is, 'Put them in the box.'" But in due course the boxes came home to South Kensington to play their part in building up our knowledge of African zoology.

Sir Harry Johnston wrote many books dealing with natural history and exploration; of these the most important are "The Kilimanjaro Expedition" (1885), "The Uganda Protectorate" (1902), and "Liberia" (1906). Lucidly written and charmingly illustrated by reproductions from the water-colour paintings of the author as well as by good photographs, these books are of permanent scientific value as sources of original information. Despite its weight and its date, the best guide that the traveller interested in natural history can carry in West Africa is the second volume of "Liberia." In addition, Sir Harry Johnston also wrote various political works, novels, and a play.

The present writer first saw Johnston at a meeting of the Zoological Society of London in 1905. He knew that appearances were often

deceptive; yet he found it hard to believe that the dapper little man reading out a long list of native names for animals in a curiously high-pitched voice could be in the sterner places of the world the strong leader of men. A broad view of this remarkable man and of his life and work seems to suggest comparison with another great pioneer of Empire---Raleigh. There are differences of course. To-day the way of the universal genius is both harder and easier than it once was; thanks to science and the press, so many have now become vocal that genius, unless it be of the narrow specialist kind, has difficulty in making itself heard above the general din and very little chance of being remembered in the restless seas of modern distraction. Had he lived three centuries ago, Johnston would have become a popular hero and he would have gone to the block; to-day, except on those rare occasions when he chanced to share headlines with the doubtful figures of a cause célèbre, Raleigh would attract little attention and would die quietly in bed. M. A. C. H.

Notices on the life of Dr. Carl H. Eigenmann, by David Starr Jordan and Fernandus Payne, in Science, vol. 65, No. 1691, give good accounts of the work of this eminent ichthyologist, able teacher, and indefatigable explorer, who died on April 24 A student under Prof Starr Jordan, he succeeded him in 1891 as professor of zoology in Indiana University, and in 1908 was made dean. For some years he was curator of fishes in the Carnegie Museum, Pittsburg, and in 1895 he established a fresh-water biological station in Northern Indiana, of which he was director up to a few years before his death. One of his most important works is on the blind cave fishes of North America, and for the purpose of collecting material for this study he made expeditions to the cave regions of Indiana, Kentucky, Missouri, Texas, and Cuba, and for the detailed exploration of the fish fauna of the Amazon and other Brazilian rivers he made four trips to South America, besides sending students on other expeditions. In all, 195 new genera, containing about 600 species, were defined by Eigenmann and his colleagues, and his technical papers number upwards of 170. It is an interesting fact that Dr. Eigenmann entered the university as a student in Latin, but most fortunately it was not too late to change when in his second year he discovered that his tastes were zoological rather than classical.

WE regret to announce the following deaths:

Mr. G. C. Champion, who collected entomological material for Godman and Salvin for their "Biologia Contrali-Americana" and contributed largely to the published work, on Aug. 8, aged seventy-six years.

Mr. Alban H. G. Doran, who collaborated with Sir James Paget and Sir James Goodhart in the compilation of the second edition of the Catalogues of the Pathological Series in the Museum of the Royal College of Surgeons, and also prepared a descriptive Catalogue of Surgical Instruments in the Museum, on Aug. 23, aged seventy-seven years.

### News and Views.

Ar the maugural meeting of the British Association at Leeds on Aug 31 a message was received from HRH the Prince of Wales expressing regret at his mability to attend in person to welcome his successor to the office of president, of whom he says "I have reason to believe that when any one in this country digs up a bone his first instinct (subject to the intervention of the police) is to send it to Su Aithur Keith" Referring to his own presidential address at Oxford last year, His Royal Highness suggested that his choice of subject, "Science and the State," has been justified by the emphasis which was afterwards laid upon the value of scientific research to imperial development at the proceedings of the Imperial and Colonial Office Conferences. This recognition, he considered, places it beyond doubt that "more general attention for the objects of science" is in process of achievement. He expressed the opinion that an increasing measure of public support should be accorded to the British Association for the furtherance of this object. Fortunately, its powers have been very materially strengthened during the past year, through the splendid generosity of Sir Alfred Yarrow, m making it a gift of £10,000 for general purposes.

Undoubtedly, the address of the royal president of the Association at Oxford last year did much to focus public attention upon the function of the scientific worker in the social organism. It informed the non-scientific members of the community, in language perfectly intelligible to them, what science has achieved, what the nation can achieve if it applies the scientific knowledge it already possesses, and the nature of those further problems confronting the world, for the solution of which the scientific worker is indispensable. The Leeds address of Sir Arthur Keith may be said to stress the spiritual aspect of science as contrasted with the material aspect dealt with by his predecessor—It is equally remarkable for its breadth of outlook and its freedom from mitating and unnecessary technicalities and obscurities of language which mar so many addresses on scientific topics. It would be well, perhaps, if the Council of the "so-called parliament of science" would consider the possibility of msisting that at least every sectional president should also deal broadly with his particular branch of science in order that the general public and members of others sections might be in a position to appreciate its implications. Papers dealing with a highly specialised piece of research are, as a general rule, best delivered before members of a learned society. Judging from some of the sectional presidents' addresses and papers read or to be read at Leeds, it would appear that the essential difference in function between a section of the British Association and the corresponding learned society, or between the British Association as a body and the Royal Society, is not sufficiently appreciated. It happens that this year only four of the presidents of the thirteen Sections are fellows of the Royal Society, whereas usually the number is six or more.

The instructive survey of man's physical nature and history displayed by Sir Arthur Keith in his address is sure to attract close attention. The address is printed in full in a Supplement to this week's issue, and the statement it contains as to the present position of Darwin's theory of man's descent will be welcomed by a wide circle of readers. We need not follow the survey here, but there are certain aspects of the search for the elusive line of man's direct ancestry which force themselves to notice Many discoveries of remains of fossil men have been made since Darwin's day - It is remarkable how little they have helped to unravel the direct stages of the ascent of modern man, and how many have been side-tracks off the main line, so that, in the terms of the genealogical tree, the branch of modern humanity has become beset by a thicket of collateral branches. We do not yet know the place of origin of the human branch, for although the weight of evidence points to close relationship in some sort with the anthropoid group, other possibilities have been advocated, each founded on legitimate arguments Indeed, it seems as if association with one or another existing type of monkey depends upon the choice of the particular structure upon which the stress of comparison is laid. Even as regards existing man, we cannot yet trace each living race indubitably to its place of origin on the ancestral tree.

May it not be that in searching for each minute intermediate stage in a series, we search for something which may not have existed, that we are still too much dominated by the idea of the rise of species by way of the continuous minimal variations which Darwin so effectively advocated 9 Did we but understand in full the possibilities of the correlated development of parts, the difference between basal variation and correlated sequence, we might cease to expect m the development of each and every structure a complete series of nunimal gradations, and be freed from the bogey of the 'missing link.' Such difficulties do not affect the main story of the ascent of man Every discovery bearing on the problem made since Darwin's day, whether it be morphological, embryological, physiological, psychological, or biochemical, has confirmed the general thesis of Darwin that man is an offspring of the animal world and that his nearest existing relatives are the higher apes; as Sir Arthur Keith puts it, "the fundamentals of Darwin's outline of man's history remain unshaken. Nay, so strong has his position become that I am convinced that it never can be shaken."

Some six hundred delegates, of whom more than four hundred are from the British Isles, arrived in Montreal for the official opening on Aug. 22 of the second triennial Empire Mining and Metallurgical Congress. The Congress has been organised by ten separate mining and metallurgical institutes from Great Britain, South Africa, Australia, India, and Canada. At the first morning's session, the chair was taken

by Sir Robert Horne, the honorary president, who with the Honourable Charles Stewart, Canadian Minister of the Interior and president of the Congress, delivered inaugural addresses. The Congress will be divided into two sections for a comprehensive tour of all the Dominion's mining centres. One tour goes right through Canada by special train to the Pacific coast, while the other confines its attentions to central and eastern Canada. On Aug. 23, the delegates left Montreal by special train for Ottawa and the Niagara Falls. Technical sessions were held in Toronto on Aug. 25 and 26.

The Empire Mining and Metallurgical Congress has endorsed unanimously a resolution proposed by Mr. R. E. Palmer, president of the Institution of Mining and Metallurgy of London, embodying the suggestions, contained in the paper read before the Congress by Sir Thomas Holland, for the survey of the mineral resources of the Empire. Sir Thomas urged the necessity of reviewing for each unit of the British Empire the mining resources for smelting capabilities with the view of accumulating in addition to the ordinary official statistics the essential data necessary for the formulation of an Empire economic policy. The British Empire produces about a quarter of the total mineral production of the world of nearly two billion tons; but it is not independent and completely self-contained in respect of mineral requirements, and it might be desirable to carry surplus stocks of vital mineral necessities which could be drawn upon in any temporary emergency, such as, for example, in the case of nickel in the time of the War. The Congress adopted the resolution as a move towards achieving a comprehensive tabulation of the Empire's mineral and industrial resources.

A NEW forestry society, termed the Society of Foresters of Great Britain, has been founded during the past year. The idea originated amongst some of the younger forest officers under the Forestry Commission; and though it is laudable enough, doubts have been expressed as to the wisdom of taking the step so soon after the inauguration of the Commission and whilst the number of trained foresters in Great Britain is so small. There exist already in Britain the Scottish Arboricultural and the English Arboricultural Societies and the Empire Forestry Association, whilst at least three other societies can lay claim to an interest in forestry or arboriculture. Neither of the three societies mentioned above can be considered to be in an overwhelmingly strong financial position. It was perhaps natural to ask whether there was room for yet another, even though its aim and object was to restrict membership to fully-trained and qualified foresters. This qualification had to be waived and associate members admitted in order to enable the society to be started. Those interested in forestry in Great Britain will watch the new-born plant with interest, but not without anxiety. For societies of this kind cannot be maintained without funds, and the man of science and the technical officer have

many calls of this nature made upon them now-adays; and to expect a jumor or even semior officer to belong to three societies all, according to their articles of membership, among at the same end, is rather a severe trial

IT is fully recognised that a technical society of the type referred to above loses half its utility and interest unless it is represented by a journal recording both its own progress and that of the science which it represents. The new society was not unmindful of this necessity. The first number of its journal, entitled Forestry, has recently appeared. It is an ambitious publication issued in beautiful style by the Oxford University Press and contains articles\* of considerable interest. But the question at once arises in the minds of those acquainted with present costs and the habits and requirements of professional men, especially forest officers -Can the money be found to maintain this high quality, and can the interest be maintained in a publication issued only once a year · for this is the present announced intention? If issued more frequently, can the high interest of the present number be maintained? We hope that, in parliamentary phrase, the answers to these questions are in the affirmative; for old hands know that they are vital to success.

It is expected that some two hundred organisations will be represented at the fourth conference of the Association of Special Libraries and Information Bureaux which meets at Trmity College, Cambridge. during the week-end Sept. 23-26. Following reception by Sir J. J. Thomson, Master of Trinity, Sir Geoffrey Butler, senior M.P. for the University of Cambridge, will deliver the presidential address, whilst among the many well-known experts giving papers are Sir Henry Lyons (Director, The Science Museum), Mr. A. E. Overton (Principal, Board of Trade), and Sir Richard Gregory. The subjects to be discussed at the Conference include such topics as the recent Report of the Public Libraries Committee, co-operation between libraries, and book selection in science and technology. Sectional meetings will be held on information and statistics in commerce and industry, on patent classification and on information bureaux questions. The Conference is open to all interested, whether members of the Association or not; a copy of the detailed programme and other particulars can be obtained from the Secretary, Aslib, 38 Bloomsbury Square, London, W.C.1. With the assistance of the Carnegie United Kingdom Trustees, the Association is publishing in the autumn a directory of sources of specialised information, edited by Mr. G. F. Barwick, late Keeper of Printed Books at the British Museum. The book is unique in character inasmuch as it records under thousands of subject headings the various centres in Great Britain and Ireland to which those in search of specialised information

THE importance of the issues involved in prehistoric chronology and archæology must be our excuse for a

further reference to l'affaire Glozel The scenticism of l'Abbé Breuil and Mr O. G. S. Crawford has received further support from M. A. Vayson de Pradenne in the Bull. de la Société Préhistorique Française, No 6, M. de Pradenne, a personal friend of Dr Morlet, has visited Glozel, himself excavated on the site, and carefully examined the collection of engraved bone objects, pottery, clay tablets, and stone implements in the collection of the peasant Fradin through whom the site was brought to light and of Dr. Morlet himself, by whom it was made known to the scientific world. So far from concurring in the Magdalenian or derived Magdalenian origin of this remarkable association of alleged prehistoric objects, M de Pradenne in convinced that they are not ancient. Two points in his investigation are particularly striking. The material of the bone objects exhibits none of the marks of a high antiquity. Its character is either that of fresh bone which has been boiled, or old but not ancient bone which has been exposed to the weather, and the marks on it have evidently been made by a metal implement, and he formed the conclusion, which he verified in the case of an implement that he himself unearthed, that the soil immediately surrounding the objects found was not in the same state as that of the rest of the stratum. This latter opinion was formed after investigating the harder as well as the looser strata. M de Pradenne's relations with Dr. Morlet add weight to his views. It seems unlikely that we shall hear anything more of this site worthy of serious consideration in contradiction of the conclusions which have now been formed after a fair and, we think it may be affirmed, impartial examination of the facts. It is scarcely necessary to emphasise the harm done to archaelogical science by the hasty and ill-considered world-wide dissemination in the daily press of sensational alleged discoveries which prove on investigation to have no foundation.

TRINITY HOUSE IS now constructing radio beacons for assisting navigation at various points round the English coast. These beacons send out distinctive radio signals at regular intervals and thus are intended to enable vessels fitted with direction finders to determine their position. During darkness and in foggy weather, these installations will be a great aid to marine navigation when ships are approaching land and will add appreciably to the safety of life at sea. The first beacon station to be put into commission by Trinity House is situated at Round Island in the Scilly Isles. It is operated on a wave-length of 1000 metres (a frequency of 300 kilocycles), which will be the standard for radio beacons. It has been designed by the Marconi Company to the specifications of Trinity House. It is automatically controlled by a master clock and transmits groups of continuous wave-signals—in the case of Round Island the letters GGG in Morse code—at predetermined Every precaution has been taken to diminish the risk of a breakdown. All running machinery, including the master clock, is duplicated. If a valve burn out it is immediately replaced automatically and a warning signal notifies the attendant. The radio mast consists of a steel lattice tower 60 feet high, and the aerial is supported at a height of 50 feet. The signal for 'Fair' weather consists of the call sign repeated for 47 seconds, followed by a prolonged dash of 10 seconds' duration, and terminated by one repetition of the call sign, the whole transmission taking 60 seconds exactly. A silent period of three minutes then follows. In fair weather this cycle is repeated three times every half-hour. In foggy weather the one-minute transmission and three minutes silence are repeated continuously. In a normal ship's receiver, the bearings can be received accurately up to a distance of about 100 miles.

PROF. EDWARD WESTERMARCK has accepted an invitation to deliver the Frazer Lecture at Glasgow in 1928. It will be remembered that the lectureship is vested in four universities in Great Britain in rotation and this time the election falls to Glasgow. In view of the fact that the British Association will be meeting in Glasgow in 1928, the University has decided that the date of the lecture shall coincide with the date of the meeting, in order that those may have an opportunity of attending the lecture who otherwise might not be able to travel so far as Glasgow at another time.

LORD MORTON'S chestnut mare, which is supposed to have produced a quagga-horse hybrid about 1814, and afterwards to have produced, by a black Arabian stallion, three bay foals resembling the quagga in some of their markings and in having more or less erect manes, has long been cited as evidence of telegony. The inheritance of coat colour in horses is now known. Chestnut is recessive to all other colours, and the series runs grey, dun, bay, black, chestnut, grey being dominant to all others. Prof. Cossar Ewart has shown that in zebra-horse hybrids, the horse colours are dominant to those of the zebra. It is also well known that horse-donkey hybrids take the colour of the horse. In the light of these facts, Mr. James Wilson (Sci. Proc. Roy. Dublin Soc., vol. 18, No. 41) concludes that the quagga was not the father of the supposed quagga-horse hybrid, since the latter was bay while the mother was chestnut, and could only produce a bay foal by a bay, dun, or grey father. Hence any evidence of telegony falls to the ground.

The International Hydrographic Bureau, of which the principal maritime nations are members, is chiefly concerned with the co-ordination of surveys and chart production. The latest issue of the *Hydrographic Review* (vol. 4, No. 1, May 1927), which is published by the Board at intervals of about a year, contains articles on the organisation, equipment, and methods of the Norwegian, Swedish, and Danish Hydrographic Services, and on various subjects germane to navigation and cartography. Amongst these, Rear Admiral A. P. Niblack, U.S.N., presents a plea for the extension of oceanographic research, particularly the study of ocean currents, which are of international interest, and the study of which is intimately linked with marine biology, meteorology, and fishery research.

The review contains a bibliography of contemporary publications and articles concerning oceanography in the widest sense of the term, this should be of value to all who are interested in the science of the sea.

APPLICATIONS are invited by the Zoological Society of London for the Anatomical Research Fellowship, tenable for three years with a possible extension for two further years, of the annual value of £400, and for an Aquarium Research Fellowship, tenable for three years, of the annual value of £350. Applications must be sent to reach Dr P Chalmers Mitchell, Zoological Society, Regent's Park, NW8, before Nov. 1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :-- An Inspector of Agriculture in the Sudan Department of Agriculture and Forests-- J Nield Cameron, Old Vicarage, Wetherby, Yorks. (Sept. 15). An assistant lecturer in mechanical engineering at King's College, London-The Secretary, King's College, Strand, W.C 2 (Sept. 16). A graduate assistant in the Information Bureau of the British Cotton Industry Research Association—The Secretary, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester (Sept. 17). A lecturer in mining at the Denbighshire Technical Institute, Wrexham-The Secretary and Director of Education, Education Offices, Ruthin (Sept. 17) A reader in pathology at Westminster Hospital Medical School—The Academic Registrar, University of London, South Kensington, S.W.7 (Sept. 23). A jumor technical officer at the

Royal Augraft Establishment for work in the specification section of the Wireless and Photographic Department -The Chief Superintendent, RAE., South Farnborough, Hants (Sept. 24, quoting No A 210) A professor of chemistry and a professor of English language and literature in the University of Melbourne - The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, W.C 2 (Oct 1) Two assistants, one male and one female, in the Plant Pathological Laboratory of the Ministry of Agriculture and Fisheries, Harpenden—The Secretary. Ministry of Agriculture and Fisheries, 10 Whitehall Place, SW 1 (Oct 1). A lecturer in biology and a lecturer in chemistry in the University of Western Australia-The Agent-General for Western Australia, 115 Strand, W.C 2 (Oct. 1). A research fellow m bacteriology at the Lister Institute of Preventive Mediene-The Secretary, Lister Institute of Preventive Medicine, Chelsea Bridge Road, S.W.1 (Oct. 8) A professor of mathematics and a professor of education at Raffles College, Singapore CA (N), The Secretary, Board of Education, Whitehall, S W 1 Scottish candidates (N), The Scottish Education Department, Whitehall, S.W.1 (Nov. 1). An assistant in the Research Department, Woolwich, under the directorate of metallurgical research. The Chief Superintendent, Research Department, Woolwich, An assistant lecturer in economics in Auckland University College—The High Commissioner for New Zealand, 415 Strand, W.C.2. A chief assistant in the Domestic Science department of Battersea Polytechnic The Principal, Batterson Polytechnic, S.W.11.

### Our Astronomical Column.

COMET GALE.—Mr. Walter F. Gale, the discoverer of comets 1894 II. and 1912 II., has sent particulars of the discovery of comet 1927 f. He was sweeping the neighbourhood of Theta Piscis Australis with a Zeiss binocular just after midnight on June 7, and picked up a small faint nebulosity, the comotary character of which was quickly verified with his telescope He obtained approximate positions on the next three nights (incidentally these positions suggest that Prof. Gonnessiat's observation of June 10 was inadvertently telegraphed half a degree too far north); these, together with a rough position on June 25 by Townsend at Hawera. New Zealand, afford material for an approximate orbit, which Dr. A. C D. Crommelin has deduced as follows: T: 1927 June 14·30 U.T.;  $\omega$ : 212° 35′;  $\Omega$ : 66° 38′;  $\imath$ : 12° 40′, log q 0 1030. The small value of i suggests the possibility that the orbit may be periodic. The distance from the earth at discovery was 0 43 astr. units. The comet still remains too far south for convenient observation in England. Some observations were made at the Cape, which have been sent to the I A.U. Bureau at Copenhagen. It is noteworthy that three of the four unexpected comets discovered this year are due to British observers, as is also the detection of Comet Grigg-Skjellerup on its return

Later.—The Cape observations, now to hand, suggest that Gonnessiat's declination is right and Gale's

wrong.

VENUS.—Mr. H. McEwen, director of the Venus Section of the British Astronomical Association, contributes an interesting paper to the July issue of the Jour. B.A.A. He quotes the radiometric measures

of Coblentz and Lampland from which Monzel deduced a surface temperature of 122" F., which bears\* to that of the earth the proportion of the inverse squares of distances from the sun. He also uses the temperature measures to advance an argument in favour of the period of rotation and position of axis announced by Prof. W. H. Pickering; the period was about 3 days, and the inclination so high that the tropics would be within 5° of the poles. Under these conditions the poles would be for most of the time the hottest regions of the planet, for they would have a very high sun continuously for a large fraction of the planet's year. The measures indicated that one cusp was much hotter than the other, this being the one where the sun was setting, whereas the other had cooled during the night. The spring equinox of the northern hemisphere is stated to occur when the planet's heliocentric longitude is 316°6, the other seasonal points being found by successive additions of 90°

Pickering's view is that the planet is practically covered with oceans, so that there would be no surface markings of a permanent character. Those that are seen are presumably atmospheric. Mr. McEwen shows that their changes are in good accord with the atmospheric circulation that would result from such an axial pose. When the pole is nearly central on the disc, there would be little rotational velocity in the line of sight; but this should be appreciable when the pole was near the limb.

The writer has made out a good case for the view he advocates, and it may at least be adopted as a working hypothesis. The rotation has long been a puzzling enigma, and any further light is welcome.

No. 3018, Vol. 120]

### Research Items.

Dreams in Africa —In Man for August, Mr. J. P. Driberg records a number of dreams of different types and their interpretation which he has collected, at the suggestion of Prof C G Seligman, among the Lango and Didinga of the south-eastern Sudan The Lotuko-speaking Lango provide eleven varieties of dream, the Didinga fourteen. Among the Lango no greater significance attaches to the dream of a magician than of a layman, but among the Didinga, although the magician does not have a different class of dream from that of the layman, all his dreams have a greater significance, and if the significance is ill-omened a sacrifice must be made of a bull or a goat to avert the threatened evil Among both peoples the significance of many of the dreams is a simple prognostication. For example, among the Lango a dream that some one kills the dreamer is considered a true forecast, to dream of killing an elephant means that one will do so, among the Didinga, to dream of hunting means that success on the next expedition will correspond, and so forth. Certain dreams, however, have a special significance the Lango, to dream of being carried away in a flood causes the dreamer fear, though whether this is because of an ill omen is not clear. To dream of being bitten by a snake is a very bad omen. A piece of charcoal must be bitten and spat out and the dreamer must prick himself with a thoin Among the Didinga, a similar use of charcoal and thorns follows on a dream that A kills B by witchcraft The dreamer must the next day call on B, bite a piece of charcoal and spit it on B, rub soot on his forehead and scratch him with thorns. The same procedure follows a dream that 1 accidentally spears himself; but it must be done immediately on waking even if this involves a journey in the night. To dream of falling in the fire must be followed by the sacrifice of a white goat and the tying of a goatskin bracelet on the person of whom one dreams.

Beth-Shan in 1926.—In the Museum Journal (Philadelphia) for March, Mr. Alan Rowe surveys the work carried out by the Palestine Expedition of the University of Pennsylvania at Beisan in the season of 1926. In addition to the actual work of excavation on the Tel and in the vast cemetery to the north, a comprehensive survey of the area was made, which showed that the original top of the mound was 346 ft. below the level of the Mediterranean, and the height 213 ft at the north and 134 ft. at the south Eight successive periods are represented by superimposed layers, but the occupation of some of the principal buildings extended from one period to another, they being used over and over again. For example, the two temples of Rameses II, which are identified as the House of Astaroth and the Temple of Dagon of the Bible, and belong to the fifth level dated 1295-1225 s.c., were used until at least Israelitish times, say 1000 s.c. The period covered by the eight levels extends from some date before 1412 B.C. not yet determined down to modern times In 1926 all the strata from the second to the eighth were worked. Up to the present that of Amenophis III, the seventh, is regarded as the most important. The material recovered from this level admits of certain inferences of great historical importance. Among the finds are a number of inscribed Syro-Hittite cylinder seals, a bronze Syrian dagger, and a Hittite axe-head of which one end is in the shape of a hand with outstretched fingers, unique but similar to an axe held by a Hittite king on a sculpture at Boghaz-Keui. This affords supporting evidence of the extent of the advance of the Hittites known to be taking place at about this time into North Syna—Further, the model of a chain or throne of Cretan (Minoan) type with Egyptian emblems and a model of a table, also of Cretan type, doubtless parts of a group of cult objects, with other finds, point to an infiltration during the Bionze Age of Ægean influence via Cyprus, of which the final phase was represented by the domination of the non-using Philistines—This Ægean-Cypriote influence in the old religion of Palestine was not recognised fully before these discoveries at Beth-Shan

The Insects of Samoa —Reference has recently been made in these columns to a monograph dealing with the insects and other land arthropods of Samoa that is being issued by the British Museum (Natural History) This work is based upon collections made by Dr P. A Ruxton and Mr. G. H E Hopkins, who visited the islands under the auspices of the London School of Hygiene and Tropical Medicine in 1924-25. Within the last few weeks three new tascicles of this monograph have come to hand Micro-lepidoptera are dealt with by Mr. E. Meyrick and his contribution forms Fasc II of Part 3 It appears that scarcely half-a-dozen named species of these insects were recorded from Samoa before the recent of the present collection, which raises the total number to 137. Of these, two-thirds of the species are endemic, and the remainder also occur elsewhere, being probably introduced through shipping. Mr. Meyrick concludes that Samoa constitutes, by the test of specific endemicity, a perfectly distinct and isolated faunal region. Another noteworthy feature is the total absence of representatives of the families Pterophoride and Ecophoride from the indigenous fauna. Part 2, Fasc. I. is devoted to certain families of Hemptera. The Fulgoroidea are dealt with by Mr. F. Muir, who finds that eight families, twentyseven genera, and fifty-one species are now known from the islands. He describes a new genus, Buxtoniella, the systematic position of which appears to be an enigma but it is relegated to the Lophopida. The Psyllida are reported on by Prof. D L. Crawford, and Mr F. Laing has dealt with the Coceda, Aphidide, and Aleyrodide. Part 7, Fasc I. contains Mr (4. F. Hill's account of the Termitide and Lieut. Col. Fraser's description of the Odonata.

ACCELERATION OF PLANT GROWTH.—At the Boyce-Thompson Institute for Plant Research in New York, experiments are being carried on for the purpose of investigating the conditions necessary to accelerate plant growth In a News Bulletin recently issued by Science Service of Washington, Dr. John M. Arthur gives a review of the work being carried on. - The results include spring wheat harvested 35 days after sowing, red clover in flower 38 days after seeding, and a large head of lettuce grown in three weeks. These remarkable results have been obtained by the use of artificial light, heat, and atmosphere process of photosynthesis in a plant is somewhat inefficient, only about one per cent. of the radiant energy falling on its leaves being utilised More than a century ago de Saussure showed that green plants could utilise more carbon dioxide than is actually available in the atmosphere, but no application was made of that fact until the War. Then, under pressure of food shortage in Germany, processes were perfected by Riedel and others for scrubbing gases from combustion of coal, coke, and charcoal to produce carbon dioxide, which was piped into greenhouses among growing plants. With high temperature and high light intensity, a concentration of less than 0.5 per cent of carbon dioxide (the normal amount present in the air is 0.03 per cent.) just about doubled the dry weight of plant tissue produced. Similarly, many plants can use more light than they get in Nature. If such plants are kept continually under an arc lamp, or if artificial light is used to supplement daylight, their growth is hastened. Wheat and clover can stand 24 hours of light a day. The tomato, however, grows fastest with 12 hours of daylight supplemented by 6 hours of artificial light. Unfortunately, commercial application of these facts is not yet in sight, and will not be until electrical power can be produced at a much cheaper rate than at present.

WEED SPRAYS —Mr A. Aslander, in the Journal of Agricultural Science, vol. 34, p 1065, describes some interesting experiments with weed sprays. Cornellian oats and field mustard (Brassica arrensis) were grown together in pots and sprayed when the mustard had developed four leaves. Concentrations of 5-15 per cent. of iron sulphate and 1-2 per cent. of sulphuric acid were used, and after the treatment the pots were kept under various conditions of humidity In all cases the oat plants were uninjured by the sprays, but the effect on the mustard varied. Iron sulphate was only effective when the relative humidity was high (100 per cent.), a 5 per cent. solution completely killing the plants in twenty-four hours under such conditions, whereas in dry air (relative humidity 30-60 per cent.) concentrations up to 15 per cent. were used without injury. The effectiveness of sulphuric acid, however, was much less dependent on the humidity, though the best results were obtained in dry air. The plants were completely killed by 1.5 or 2 per cent. solutions, the higher concentration being necessary if the soil in the pots had been kept dry. Temperature had a marked influence on the effect of the spray. Whereas at 30° C., a 2 per cent. solution proved tatal after one hour, at 60 ('., the same result was only obtained after five hours. Artificial rain, produced by sprinkling the plants with water, failed to decrease the action of the acid; Experiments with Elodea canadensis bore out the spraying results with mustard, since protoplasmic streaming continued for two hours in a 10 per cent. solution of iron sulphate, but ceased in 30 seconds in I per cent. sulphuric acid.

NEMATODA OF THE LEIDY COLLECTIONS .-- A. C. Walton has examined the extensive collection of Nematoda made by the late Dr. Joseph Leidy and presents the first of a series of reports on this material (Proc. Acad. Nat. Sci. Philadelphia, vol. 79, pp. 49-163; 1927). The worms were obtained chiefly from American hosts, but a few were from imported animals in captivity in America. Many of the original Leidy species are present in the collection, and in some cases it has been possible to designate type specimens. The main interest of this account is that it contains descriptions with drawings of species which, since Leidy's time, have been either unrecognised or but doubtfully identified by later workers. More than a hundred definitely recognised species are recorded, twenty-four of which are described as new. Appended is a list of hosts and their respective Nematoda.

OIL IN MUD FROM SEA-FLOOR.—Some interesting research on the oil-content of sea-bottom muds and sands accumulating at the present time is being conducted by Dr. P. D. Trask, of the American Petroleum Institute. Samples of muds were taken from shoalwaters off the coasts of Southern California and North Carolina; such samples are then subjected to destructive distillation and other chemical and physical tests.

According to Science Service, No. 326 F. Washington, D.C., of June 25, 1927, oil was produced from all these types of sediment; "the yield was low, and in general varied in amount with the degree of fineness of the sediments, ranging from a maximum of 2.7 gallons per ton in a clay-silt to almost nothing in a sand. This maximum yield of 2.7 gallons per ton is but 5 or 10 per cent, of the amount obtained from the better grades of oil shale, which ruin from 30 to 50 or even more gallons per ton." This work has obvious bearings on modern theories of the origin of petroleum, particularly those which invoke marine mother-substance and primary environment; so far it is only in the preliminary experimental stage, but it is backed by a grant from the John D. Rockefeller fund of the Institute, and exhaustive investigations along these lines are contemplated.

IONISATION POTENTIALS OF MERCURY - Dr E. O. Lawrence, who recently obtained very strong evidence that the ionisation potential of mercury was multiple, with at least four distinct types of melastic electron impacts between 10.6 volts and 12.1 volts, has described experiments in the July number of the Journal of the Franklin Institute, in which he has confirmed this with different apparatus. In the earlier form, he obtained a homogeneous pencil by magnetic sorting: with the present arrangement he has worked with electrons from an oxide-coated filament, with a thermal distribution of velocities. He used very small electron currents, of the order of 10<sup>-9</sup> amp., and measured the positive ion currents by a null electrometer method, employing a slightly modified Lenard system of fields. There is little doubt that the effect is real, and not due to some action of magnetic fields, or to diffusion of positive ions, but it would be interesting to repeat the work with other monatomic gases, and with a continuous variation of the accelerating potential.

OPTICAL ISOMERISM. In a recent paper in the Zeitschrift fur Physik on the quantum theory of polyatomic molecules (vol. 43, p. 805), Dr. F. Hund arrived at an interesting paradox. According to his analysis, molecules possessing the mirror symmetry associated with optical activity should not have stationary states which correspond to small displacements from the two main positions of equilibrium, but should undergo transitions between the right and left handed forms. This is evidently not in agreement with the permanence of the properties of many optically active substances. The solution follows when the expression for the average time of life in either state is evaluated numerically. This contains an exponential term involving the internal energy, and seven-fold increase of the latter could change the time of relaxation from 10 second to 10° years. It seems as if apparently stable bodies of this class are actually undergoing slow spontaneous transformation into an inactive mixture which contams equal quantities of the lavo and dextro forms.

Low-Temperature Process. The Chemiker-Zertung of July 16 contains an account, given by Dr. F. Simon of Berlin at the recent meeting of the Deutscher Kalteverein, of a new laboratory method of producing low temperatures by pumping adsorbed gases from charcoal, silica-gels, or from zeolites. Thus helium, adsorbed by charcoal and cooled by immersion in liquid hydrogen, could be further cooled to  $-269^{\circ}$ C. The process is not continuous, and is at present only available for the production of small quantities of liquid helium, hydrogen, and other gases.

A CRYSTALLINE POTASSIUM HYDROGEN DIOLEATE.

—No acid soaps of definite composition analogous to

No. 3018, Vol. 1201

the two acid sodium acetates have been shown to exist. In the Journal of the Chemical Society for June, McBain and Stewart describe the preparation of the first definite crystalline compound of this type observed with soaps. Potassium hydrogen dioleate is prepared from oleic acid and potassium oleate in alcoholic solution. Well-defined crystalline plates separate on cooling in ice. The substance shows a transition point at 43°, at which it breaks up into potassium oleate and a solution of oleate and oleic acid. On account of the ease with which it crystallises from alcoholic solution, it offers a means of purifying oleic acid.

SULPHUR DIOXIDE IN FOOD —The determination of sulphur dioxide in foods forms the subject of the Ministry of Health Report on Public Health, No. 43, recently published by H.M Stationery Office (1s 3d net). The only preservatives now permitted to be used in foods and drinks are benzoic acid and sulphur dioxide. The determination of benzoic acid has already been dealt with in Report No. 39 of this series, and the present Report deals on similar lines with sulphur dioxide. Although the Public Health Regulations specify the total amount of sulphur dioxide permitted in various foods, no distinction between free and combined sulphurous acid is made It is, however, important to know the nature and extent of the combination between sulphur dioxide and certain constituents of food, since the presence of comparatively stable compounds with sulphur dioxide will affect the determinations unless due precautions are taken. The sulphur dioxide is separated from combination on the addition of alkali or on distillation with acid. Gravimetric determination as barium sulphate gives accurate results in nearly all cases.

IGNITION TEMPERATURES AND 'ANTI-KNOCK' IN-VESTIGATIONS -The effect of small amounts of lead tetraethyl and other substances in allaying the 'knock' which occurs with some fuels under certain conditions in an internal combustion engine has evoked considerable interest. Much work has been done on the effect of various compounds on the knocking characteristics of fuels by Egerton and Clates, and we have received a series of four papers reprinted from the Journal of the Institution of Petroleum Technologists, vol 13, No. 61, April 1927, which summarises their work. The first three papers deal with the effect of metallic vapours on the ignition of substances, the significance of ignition temperatures, and the offect of certain organic compounds on the igniting and 'knocking' character of petrol. The fourth paper reviews the above work and discusses the reasons for the effects observed. It suggests processes of combustion and ignition and supplies a theory of 'anti-knock' action A full report of this work was sent to the Aeronautical Research Committee, and is also summarised in the Air Ministry's Reports and Memoranda, No. 1079, which has recently been published. The experiments show that the use of anti-knocks' retards the initial processes of combustion and the 'anti-knock' may be regarded as a negative catalyst which reacts with and removes those substances which autocatalyse combustion Ten theories which have been advanced in explanation of the action of anti-knocks are briefly described, including Callendar's nuclear drop theory (see Nature, April 9, p. 542). With regard to the latter, it is remarked that no account is taken of the chemical behaviour of 'anti-knock' compounds, and experi-ments show that more is required of an 'anti-knock' than protection or dilution of the droplet. There

is reason to expect that Callendar's suggestions may come in as a secondary effect, and by concentrating the dope in the droplets the tendency would be to enhance its effect where most required

ELECTRICAL APPARATUS FOR MINES.—A further report on flame-proof electrical apparatus for use in coal-mines, by H. Rainford and R. V. Wheeler, has just been published (Safety in Mines Research Board Paper, No. 35 London: H.M. Stationery Office). The research was made principally to discover the means of preventing the flames due to firedamp explosions which sometimes occur within the casing of electrical apparatus from passing to the outside atmosphere. Experiments were also made on the ring-relief device, which is intended to provide additional means of pressure-release when the volume contained by the casings is large. In this case neither flange nor perforated plate protection, as shown in previous reports, is adequate. The ring-relief device consists roughly of a number of metallic rings separated from one another by narrow radial distance pieces. These are assembled in the form of a cage and held securely in position by a circular brass end plate which is connected to the end plate by bolts. The interior of the casing is thus in communication with the outer air by the series of gaps formed by the separation of the rings. The general conclusion drawn from the experiments described in the report is that the use of the ring-relief device forms both a satisfactory method of releasing the pressure due to the fire-damp explosion in the interior of the electrical apparatus and also prevents the passage of the flame to the outside. The British Electrical and Allied Industries Research Association assisted in carrying out the work.

The Action of Lightning Arresters.—Devices called 'lightning arresters,' or electrical safety valves, have been in use for many years to protect electrical machines, more particularly those which are connected with overhead systems of distribution. phenomena that take place on electric lines during thunderstorms are well known. Sparks take place from conductors to neighbouring conductors connected with the earth. If the electric pressure of supply be high, an arc may be established, causing a short circuit, which may overstress the dynamos or burn out the device, leaving the system unprotected. At the recent international conference on high tension supply in Paris, Mr. McEachron, of the General Electric Co, U.S.A., gave a theory of the action of the safety-valve which explains well what happens in practice. During a thunderstorm, owing to the electrically charged clouds, quite appreciable charges of electricity are induced on the conductors. A lightning flash sets these charges free by suddenly altering the potentials of the clouds. The charges now travel in both directions along the conductors, half of the initial electrostatic energy being converted into electromagnetic energy. The potential gradient of the wave-front causes the safety-valve to act, and if a sufficient charge passes to earth in a very brief interval, the pressure drops to its working value, the valve ceases to operate, and the system again works normally. In California, a working voltage of 220 kilovolts is employed. It was thought that the necessary high insulation would completely protect the line. This it fails to do. Even when fourteen disc insulators in series are used to support the conductors, 'flash overs' occur repeatedly. This proves that the impulse voltage causing them must exceed 2000 kilovolts. The insulation only breaks down when the time of application of the applied voltage is excessive.

# Research and Industry in South Africa.

THE Union of South Africa, although possessing so small a population (1,672,000 whites), employs the scientific worker and the engineer to an exceptional extent, and progress in the Union is correspondingly remarkable. Forty years ago the country was sparsely populated and scarcely possessed a factory. In 1925 the gross value of the output of its industries was estimated at £79,789,000, and that of its mines at a further £50,000,000.

Much of this progress is directly due to the intelligent employment of scientific and engineering skill, In gold-mining, the discovery of the cyanide process made possible the present output of more than £40,000,000 a year. The handsome profits obtained, in spite of the low grade of most of the mines, have been made possible by the application of years of research and experiment to the development of metallurgical processes, the cheap production of electricity, explosives, and compressed air, and to the design and handling of rock drills and jack-hammers.

Fortunately, this is now fully realised by the financial heads of the mining industry. Apart from the central research laboratories of the groups, some of the larger mines have their own 'study departments, the staffs of which devote their full time to research, experiment, and instruction in methods likely to reduce costs. In the best mines only men with technical training as well as practical experience are employed on this work; and they are well paid.

In some countries agriculture is popularly regarded as one of the most empirical industries. In South Africa the local peculiarities of soils, the varieties and virulence of pests and diseases, and the irregularity of the rainfall, early led to a special call on the services of the research worker and of the civil engineer. In spite of the disadvantages mentioned, South Africa now exports more than ten million pounds worth of farm

products a year.

So long ago as 1911, four highly paid posts were created for research on the fertility of seeds, whilst the large veterinary research institute near Pretoria was founded in 1908. There are now, in addition, five schools of agriculture with experimental farms, and also a national herbarium. There is a department for the study of bacterial diseases of plants at Protoria, and a government laboratory at Durban for the study of the sub-tropical diseases of the sugar-cane and allied plants. Durban also possesses a private institution for research on problems met with in the sugarcane industry. At Cape Town there is a government laboratory for the study of the diseases of deciduous fruit trees.

The Department of Agriculture maintains a special experimental farm for the study of the resistance of plants to drought and frost, and also two chemical laboratories (Cape Town and Johannesburg), equipped

for both analytical work and research.

Students who wish to take up the scientific study of agriculture complete a preliminary three years in South Africa and then proceed for a further two years. usually aided by a government scholarship, either to Guelph, Ontario, or to Denmark or Sweden. Those taking up veterinary sciences for the degree of B.V.Sc. take a two-years' preliminary course at an approved college or university in South Africa, and then a threeyears' course at the Institute at Onderstapoort near Pretoria

That the application of the results of such study and research may be made to yield good profits or, alternatively, to prevent heavy losses, is now widely appreciated by the majority of the farmers in South Africa, but not by all. A story is told of one old cattle

farmer, the local oracle of his district, who did not believe in blood tests for disease. Such tests are carried out tree of charge if the suspected animal is found to be intected, whilst a small fee is charged if a negative is obtained. This farmer sent a sample of his own blood to the government laboratory and widely proclaimed his eleverness in devising this pitfall for the - --! (gentlemen) who spend the poor farmers' taxes in such foolery. In due course the report was received by him. It stated that a mistake had been made; the blood sample was not from any farm animal but appeared to have been taken from an old gorilla which was suffering from the list of diseases attached and was apparently in such a bad condition that it should be killed at once. The report also stated that, in accordance with the regulations, no fee would be charged for the examination of the sample submitted. The farmer was not heard proclaiming his views on this subject any more.

In connexion with forestry, as apart from farming, a small sylvicultural research station has been established near Knysna in Cape Colony and the establishment of similar stations is contemplated in other Timber investigations are carried out at Pretoria by the Department of Agriculture in cooperation with the Railway Administration. Relevant inquiries from the public are dealt with by the officer

of this section.

Medical research has received particular attention in South Africa, and expenditure has been on a lavish scale. Apart from the outstanding investigations on the prevention of silicosis and pneumonia on the mines, much work has been done on epidemic influenza by the South African Institute for Medical Research. Eighteen memoirs have been published on these and other subjects. The chief medical school of the Union is at Johannesburg

In mining, apart from the central laboratories of the mining groups and the efficiency and study departments of the larger mines, the Department of Mines and Industries carries out much research work. Health, safety, and particularly the prevention of mmer's phthisis, are the subjects dealt with by the latter. Recently, in conjunction with the Geological Survey, special attention has been given to exploring the commercial possibilities of mmeral deposits, particularly those of the base metals and the non-metallic minerals. The subject of uses and markets overseas receives special attention.

In chemical industry, still in its mfancy in South Africa, private enterprises have carried out a large amount of work on local problems such as the manufacture of wattle bark extract, refractories, phosphates, caustic soda, acetates, paper, starch, wood and coal distillation products, and rubber from the raw materials occurring in the Union. Promising local research is now being carried out on yet another process for the 'liquefication' of coal, and on the distillation of oil from the local shales and torbanite. Practical experience and systematic experiment have been successful in establishing the local manufacture of leather, soap, candles, calcium carbide, cement, glass, tiles, and earthenware.

The production of iron, steel, and alloy steels from local ores is only just commencing, although the utilisation of the immense supplies of scrap metal from the mines was more or less perfected during the period

of the War.

With so much interest in research, and so much development in industry, it is not surprising that South Africa has many scientific societies, most of which publish their own proceedings and maintain a high

standard in the contributions of their members. In Johannesburg an interesting venture is the Technical Club, an attempt at a social club for the members of the scientific societies which contribute to its upkeep. The club successfully houses the offices of the secretaries of the contributing societies; but as in London, scientific workers do not seem to be anxious to see each other in the evenings except at the meetings of their respective societies. At the universities, on the other hand, there is a considerable amount of social intercourse, a good esprit de corps, and keen competition in games; but in both the scientific societies and the universities the importance of research to industry and of industry to the country is keenly appreciated.

Industry already employs many thousands of whites and blacks in addition to the thousands employed by the mines With its firmly established agriculture, its fine geographical position with regard to the growing markets of the East, its vast national resources of coal and iron, its fine railways and good harbours, and its wide appreciation of the value of research, the future of the South African industries should be bright indeed.

### The Food of Young Herring.

In the investigation of the food contents of large batches of small herring (Fishery Board for Scotland, Scientific Investigations, 1927, No. 1, "Observations on the Food of Post-Larval Herring from the Scottish Coast"), Miss Helen S. Ogilvie, of the Fishery Board for Scotland, has an exceptional opportunity. The fishes examined measured about 30 mm. to 45 mm., and were metamorphosing, having a more or less transparent body with, in the larger specimens, scales in the process of formation. Hitherto it has been far more difficult to find such stages than to find the fully scaled forms which are slightly older and larger and constitute the 'white-bait'. These post-larval stages have now been found in abundance in the coastal waters and up the estuaries in the neighbourhood of Aberdeen. Lot No. I was taken outside Aberdeen Breakwater, Lot No. II off North Pier, and Lot No. III, examined for comparison with the other two, from Kincardine-on-Forth.

Observations have been made on the food of very young herring and of those of whitebait size, but not so far to any extent on post-larval herring between these stages. The present work is therefore extremely valuable. As was to be expected, the food found consisted almost entirely of copepods, the commonest species being Pseudocalanus elongatus and Oithona similis, and, in those from Kincardine, Eurytemora hirundoides in great abundance, which last is a brackish water copepod, the station where the third sample was caught being an estuarine one. One fish belonging to this group measuring 45.5 mm. contained 369 copepods. Another from Lot II measuring 40 mm. contained 479.

Miss Ogilvie finds, contrary to those workers on the younger stages who found many empty, that nearly all the herring examined were feeding. Out of 345 individuals, 95·4 per cent. contained food. In fishes of the same size examined by Hardy from the North Sea, only 46 per cent. contained food. Moreover, more food was found in the Scottish herring than in those from England. One particular copepod was the chief food in each lot. Thus in Lot I Pseudocalanus was predominant, in Lot II Oithona, and in Lot III Eurytemora. All three copepods are some of the commonest present where the fishes were respectively taken, and it seems more a matter of size than anything else which determines the species eaten.

### University and Educational Intelligence.

London.—Applications are invited for the William Julius Mickle fellowship, value not less than £200 and open to men and women graduates of the University, resident in London. The fellowship is for the student who, in the opinion of the senate, has done most for the advancement of medical art or science during the preceding five years. Applications should reach the Academic Registrar, South Kensington, S.W 7, not later than Sept. 30

Dr. R. M. Wenley, who has been acting as director of the British division of the American University Union, is about to return to the headship of the Department of Philosophy and Psychology in the University of Michigan.

APPLICATIONS are invited by the Wigan and District Mining and Technical College for the A. M. Lamb scholarship in mining, value £30 annually and tenable for three years at the full-time courses of the college. Particulars can be obtained until Sept. 7 from the principal.

Notice has been received of the Prof. Aurelio Bianchi International Prize of 10,000 lira (about 100 guineas) for "works in phonendoscopy, phonendography, phonendometry" of an experimental character. The prize is open to persons of all nationalities and to individual workers or several persons working in collaboration. Memoirs must not have been published before, and may be in Italian, English, French, German, Spanish, or Portuguese. The competition closes on May 24, 1928. Further particulars can be obtained from the Rector, Royal University of Perugia.

Titles of theses for doctorates conferred in the sciences by American universities in 1925–26 are given in a list published by the National Research Council as Reprint and Circular No. 75 (N.R.C. Washington, D.C., 50 cents). The list is classified under twenty-one subject headings, and statistics of doctorates conferred under each of these headings are given for the past ten years. During this period the number of doctorates conferred annually has increased from 373 to 740, the increase being greatest under chemistry (from 108 to 256). The Council expresses the hope that those who find the data of interest will write, so that the Council may judge whether the publication should be continued.

Bradford Technical College opens this year a new department of pharmacy, particulars of which are given in the college prospectus for 1927–28. The courses are recognised by the University of London and the Pharmaceutical Society of Great Britain for the purpose of training for the degree of bachelor of pharmacy and for the Society's professional examinations respectively. A special feature of the College is the provision made in its department of commerce and banking, established in 1925, for meeting the needs of students who will enter the commercial side of industrial undertakings or such professions as accountancy, and for equipping students in all branches of technology with a useful knowledge of economics. Three research scholarships of £100 each are offered to students proposing to stay on at the College after completing diploma courses.

# Calendar of Discovery and Invention.

September 5, 1862—James Glaisher, who was the first superintendent of the magnetical and meteorological department of the Royal Observatory on its foundation in 1840, and was also the founder of the Royal Meteorological Society, made many balloon ascents for scientific purposes, the most notable of which was that made from Wolverhampton on Sept 5, 1862, when a height of nearly seven miles was attained

September 6, 1863—It was on Sept. 6, 1863, that Philipp Reis (1834–1874), a professor of Frankfort-on-Mame, explained to the Emperor of Austria his 'telephon' for transmitting musical sounds to a distance. Reis probably designed ten distinct forms of transmitter and four forms of receiver. Some of his apparatus is to be seen at the Science Museum, South Kensington A Reis 'telephon' was also experimented with by Hughes, who exhibited the instrument to the Emperor Alexander II. of Russia at Tsarskoye Selo in 1865

September 6, 1870.—The need for the application of scientific methods in designing and building ships has often been brought home by disasters at sea, of which the loss of H.M.S. Captain is perhaps the most notable. Built on the Mersey to the plans of Captain Cowper Coles, the Captain was a fully-rigged low-freeboard turret vessel 320 feet long and 6950 tons displacement. She was completed in 1870, and after preliminary trials she joined the Channel Fleet off Finisterre, but on the night of Sept. 6-7 capsized, 475 officers and men being lost. An outcome of the tragedy was the appointment of a Committee of Design, on which Armstrong, Rankine, Kelvin, Woolley, and Froude served, while much more extensive investigations into the question of stability of ships was undertaken than had hitherto been the case

September 7, 1807.—Winsor's success in lighting Pall Mall with gas in January 1807 had far reaching effects and also led to extravagant speculation. Winsor himself lectured and gave demonstrations, and on Sept. 7, 1807, Lady Bessborough, writing to the Earl of Granville, said. "Winsor promised a return of 6000 guineas a year for every guinea subscribed. No fewer than 17,000 shares were sold in ton days, and Pall Mall was blocked with people in carriages, on horseback, and on foot rushing to invest."

September 8, 1859.—After many delays, the famous Great Eastern proceeded down the Thames on trial on Sept. 8, 1859. She had then been five years under construction. About as large as our present Mauritania, her machinery was only about a seventh of the power. She had both screw and paddles, but her combined horse-power was only some 9000 H.P. Moreover, she had but 25 lb steam pressure in her boilers, and her coal consumption was very high. It was the backwardness of marine engineering that, as much as anything, made it impossible to make her pay.

September 9, 1892.—"On Sept. 9, 1892, Mr. [Prof. E. E.] Barnard was studying Jupiter with the large telescope at the Lick Observatory, which has an aperture of three feet, and as the light of the planet produced too great an illumination of the field of vision, he carefully intercepted it, whereupon he noticed a feeble luminous point nearer than the first satellites. At first he thought it was a small star, but as the days passed all such doubts were removed, and it became clear that here was indeed a fifth moon, situated at no greater distance than 113,475 miles from Jupiter's enormous globe. . . Few observers are powerfully enough equipped to perceive this tiny world, whose diameter is only some 90 miles" (Moreau).

### Societies and Academies.

Paris

Academy of Sciences, July 25 André Blondel. Abacus for the resolution of the general equation of the third degree and the discussion of the differential equation of the third order with constant coefficients. Paul Sabatier and Antonio Fernandez Dehydrogenations and hydrogenations catalysed by metallic oxides. In previous communications the catalytic behaviour of various metallic oxides has been mamly studied by the reactions with alcohols. Pipendine has now been submitted to similar experiments The reduction of nitrobenzene and alkyl nitrites by hydrogen in the presence of manganous oxide or zinc oxide has also been studied D Wolkowitsch. A geometrical interpretation of Castigliano's theorem in a particular case—G. Pfeiffer: The construction from a system of partial differential equations of the first order with an unknown function, of an equation, lmear in Jacobians, satisfying Hamburger's conditions, and also of a system of equations, linear in Jacobians, for which the generalised conditions of Hamburger are fulfilled. Serge Bernstein The The multiply monotone polynomials which deviate the least from zero A. Veronnet: The most general movement of an isolated heterogeneous fluid mass, which keeps an invariable form. The trajectories are circular and the level surfaces of revolution. -Swyngedauw: The unfolding of belts. D S. de Lavaud. The stability of the vibrations of the front axle and wheels of a motor-car. Rebillet · Carburation in internal combustion motors. A general formula is given for the weight of air drawn into the motor in a given time and a mechanism described and illustrated by means of which the petrol injected can be made to follow the same law. Léon Kuste. The practical limit to increase of size of commercial aeroplanes. E. M. Antoniadi. Recent observations of the planet Mercury with the Meudon 83 cm, telescope

Carl Stormer: Remarkable action of sunlight on the height of the autrora borealis. On Sept. 8, 1926, the height of an aurora measured on a 26 kilometre base at Oslo was found to be 300 km, 500 km, above the earth, instead of the average 80 km, 200 km. This aurora was directly exposed to sunlight, and examination of earlier data showed that a high aurora was usual when exposed to the rays of the sun. The spectrum of the high aurora gives lines in the blue and violet which are not shown by the low altitude aurora H. Deslandres: Remarks on the preceding communication. Mlle J. Clavier. Study of the reflecting power of some unoxidisable steels. Four non-rusting steels were examined and their reflective powers measured for eight different wavelengths. One group of mirrors was exposed to the air for two months; the other group was kept away from air and moisture. The measurements were practically identical and show that these steels possess the qualities of a good material for reflectors. -G. W. Ritchey and Honri Chrétien: Presentation of the first model of an aplanatic telescope. Edmond Bayle and Lucien Amy: The application of spectrum analysis to the detection of metallic impurities. A modification of the method of Jolibois and Bonnet, m which the metal is first deposited electrolytically. A list is given of the minimum amounts of various metals capable of detection by this method, varying from  $1 \times 10^{-6}$  gm. of silver to  $1 \times 10^{-10}$  gm. of manganese.—L. Dunoyer: The measurement of the gases dissolved in water. The method is based on the evaporation in a high vacuum of a small quantity of water (1 c.c. to 2 e.c.), absorption of the water

White the money property of the

vapour by phosphorus pentoxide, and measurement of the pressure produced by the evolved gas results are higher than the figures usually accepted -A Colani Study of the systems uranyl sulphate, alkalme sulphate, water, at 25° C—Félix Taboury
The basic carbonate of beryllium. The decomposition of the ammonium beryllium carbonate does not give the substance indicated by Debray, but a more basic carbonate still containing ammonia Even after prolonged washing with water charged with carbon dioxide, it is extremely difficult to remove the whole of the ammonia —Max and Michel Polonovski A scopinium derivative. reduction to  $\psi$ -scopine and degradation to m-oxybenzaldehyde —Emile André and Mile. M. The François. Contribution to the study of the marine animal oils. Researches on the unsaturated fatty alcohols of spermaceti oil—Mine. Ramart, Mlle. Laclôtre, and M. Anagnostopoulos The action of the organo-magnesium compounds on the a-trisubstituted primary amides Whilst mono-and di-substituted acetamides give ketones when condensed with organo-magnesium compounds, the trisubstituted acetamides yield nitriles —Raymond The solubility of 1-phenyl-2 3-dimethyl-4 - dimethylamino - 5 - pyrazolone in water — Branco Dimitrievitch · The conditions of deposit of the axinite of Mont Avala (Serbia) -Ch Mauguin. The study of muscovite mica by means of the X-rays.—P Corbin and N. Oulianoff The difference and the resemblance of the crystalline schists of the two slopes of the Chamonix valley (massits of Mont Blanc and Aiguilles Rouges)—Jean G. Popesco: A variation of terrestrial magnetism.—A. Lebediantzef: The modifications of the introgenous substances in earth dried in the open air and left fallow.—A. Mordvilko · Anolocyclia in the Pemphigus of Pistachia.-F Henrijean. New researches on the heart and the electrocardiogram -Philippe Fabre: Relation between the linear constant and the chronaxy. (h. Champy and Th. Keller · Uterme and mammary development by mjection of ovarian hormone.—J. Houget, Andro Mayer, and L. Plantefol: A particular form of biological oxidation.—L. Margaillan Remarks on the oil of grape pips.—R. Fosse and Mllc. V Bossuyt The estimation of allantoic acid as xanthylurea. Application to the analyses of the leaves of Acer pseudoplatanus.

#### SYDNEY.

Linnean Society of New South Wales, June 29 -G. H. Cunningham The Gasteromycetes of Australasıa (Part vii.). The genera Disciseda and Abstoma Under Disciseda eight species are placed, one being described as new Under Abstoma are placed two species, one being confined to New Zealand, the other, hitherto undescribed, being confined to Australia (Part viii.) The genus Mycenastrum The single species M cornum is fully described and its great variability indicated —E C. Chisholm. Additional flora of the Comboyne Plateau, 1926.—G H. Hardy. (1) Further notes on a new classification of Australian robberflies (Diptera, Asılıdæ). The whole family Asilidæ is dealt Three subfamilies and seven tribes are recognised. The old subfamily Laphrina is divided, two of the genera being incorporated in the Saropogonini, the remainder forming a new tribe. (2) The phylogeny of some Diptera Brachycera. Tabanoidea, Asiloidea, and Empidoidea are dealt with and special attention is given to the first two. The families Therevidæ, Apioceridæ, and Mydaidæ are closely related to the Saropogonini tribe of the Asılıdæ; also the genus Clesthema, previously regarded as a Therevid, may be an off-shoot from a stock of the Asılıdæ much more primitive than the Saropogonini.

### Biology and the Race.

THE presidential address to the South African Association for the Advancement of Science, delivered by Prof. H. B. Fantham at Salisbury on June 29, deserves perusal by all interested in the broader problems of biology in its relation to national polity. There are probably few biologists who will regard as unjustified the note of pessimism which makes itself heard here and there in the address: there are equally few who will fail to recognise its common sense and constructive value, or to admit that much of what is addressed to South African listeners is well worthy of attention in Great Britain.

Dealing first with the immense spread of education in western Europe and America during the last six or seven decades, Prof Fantham asks, Has it fulfilled its expectations? This question must be answered in the negative, not, however, that education is itself at fault, but rather that the swarming into the universities of all and sundry m search of a vocational training has brought with it the development of the examination system with its resultant overwhelming of the truly educative by the merely informative function. Initiative, instead of being developed, has been diminished or killed, and the universities, from being the homes of culture and the training-grounds of leadership, have tended to become mere trainingcolleges for the professions. The universities in turn react upon the schools owing to prospective teachers concentrating their attention upon such subjects as, at the moment, 'pay.' During training in the technique of teaching due attention is paid to drill in the 'principles' of education and psychology, but little to the fact that without solid biological foundations such principles are liable to be no more than the fleeting fads and hypotheses of the day. The teacher is told to 'follow the child': to make study interesting instead of to make the pupil interested in study. He is unimpressed by the important need to make the child fit into his biological environment by attention to the so-called small things of life—politeness, tidiness, consideration for others, the team spirit, the avoidance of sloppiness-mental, moral, or physical.

The instilment of biological principles into the school curriculum means the development of common sense, the appreciation of cause and effect, the development of personal effort, personal observation, personal thinking—all as different as possible from the familiar product of the present

day with its absorptiveness of what is served up to it, its responsiveness to popular catchwords and slogans, and its belief in conferences and committees.

No section of Prof. Fantham's address is more deserving of serious consideration than that in which he directs his attention to some of the sociological difficulties of the day. He points out the impossible handicap to which the white race is submitting itself by the ever-growing burden of social services with their crowds of officials. Amongst the most costly of these services is school education, but this burden is not incapable of being 'Frill subjects and snippets' should lightened be eliminated or paid for by the parent. It is suggested that the education provided free by the State should be restricted to 'the three R's,' the study of the mother tongue—including grammar and composition, the general elements of observational and experimental science, with needlework and cookery for girls, together with a cultural subject, such as singing. Secondary education should not be free—it is a curious human weakness that what is not paid for is not appreciated—but generous help should be available in the way of scholarships to those who are mentally qualified to take full advantage of them.

It is perhaps prudent to hesitate before we dismiss all this as old-fashioned, and to ask ourselves seriously whether there is not contained in it a very large infusion of common sense.

Prof. Fantham, being a distinguished South African biologist, we naturally turn with special interest to what he has to say on the colour problem, for there are few problems in which attempts to reach a true solution have been more interfered with by the intrusion of sentiment uncontrolled by scientific knowledge. Here we have the opinion of a biologist who realises, as all biologists do, that the black skin of the negro is the outward expression of profound differences of a more obscure kind, which mark him off from the white race as distinctly as does his non-attainment of what we call civilisation, with its complex social organisation, its great cities, its high art, its written language, during all these untold centuries of his undisturbed sojourn in Africa.

Prof. Fantham has no doubt that the proper line of policy is that of social segregation of the two races. Racial admixture is disastrous in its results. "When once chromosomes of Bantu origin get mingled in white families they cannot be bred out, as is so often popularly supposed, but will exhibit themselves in unfortunate ways

and at unfortunate times throughout the ages. What we have to do is to make the black man a happier and better black man, not to attempt to make him an imitation white man. He is a country man. He should be settled in the country and trained in practical agriculture, in hygiene and sanitation. He should not be brought into towns and made to do all the manual labour of the whites—with the resultant encouragement of sloth and idleness amongst them.

It will be seen that Prof. Fantham's address deals with matters that have been much in the air As the columns of Nature have at the moment repeatedly testified during the last few months, the rôle of science in the school education of the citizen is attracting at the present time much attention and giving rise to much discussion. Not infrequently in the course of such discussion the main issue tends to be obscured through the persistent failure to keep distinct in the mind the two main functions of education—the first in importance, as it is in time, that of educating in the strict sense, of developing to the highest possible extent all these various capacities which combine to produce all-round ability, such as accuracy and rapidity in observation and the accumulation of experience, involving on one hand skill in actual observation, and on the other, skill in drawing rapidly and accurately sound conclusions therefrom; and the second, that of providing the mind with a store of knowledge and Although the boundary between these two functions of education is naturally not a sharp one, it is imperative in order to secure clarity of discussion that its existence should not be ignored.

As a matter of fact the educational utility of the two main branches of science - physical on one hand and biological on the other- is related to these two main functions of education. As a discipline for the young child, to develop the powers of observation and of reasoning upon the basis of observation, it would appear unquestionable that it is the physical division of science that is the more useful. By it alone are provided those simple types of observation, capable of exact measurement and of repetition over and over again under approximately the same set of conditions, which are necessary for the best training in observational accuracy. Moreover, the mathematical methods employed in the treatment of its observations afford a quite unrivalled training in logical reasoning.

It is, on the other hand, in the later task of school education, that of turning out the wellinformed citizen, that the claims of biology to play an important part are quite irrefutable. In a complex modern State, with its citizens linked together into a biological whole of the greatest complexity, depending for its continued existence upon the applications of biology to food-supply, sanitation, medicine, surgery—its everyday discussions and conversations dealing with subjects like evolution, genetics, birth-control, heredity, public health, and so on—it is clearly absurd that the citizen should not be provided with the foundation of biology without which such discussion is apt to be not merely futile but actually harmful.

While probably all qualified by their own experience to form an opinion will be in agreement up to this point, there is unfortunately up to the present no agreed scheme of instruction in elementary biology for schools. The best of such courses as do exist in a few of the great public schools are commonly modelled upon what is required for the first MB examination. Even for its own special end—that of providing a sound foundation of scientific biology for the superstructure of the medical curriculum—this type of course is looked at askance by many competent judges, but quite certainly it is not what is required by our ordinary budding citizens What is required for the education of the general citizen is not a mass of details regarding the 'insides' of men, or rabbits, or crayfish; it is not a collection of packets of ignorance or very incomplete knowledge done up in wrappings of polysyllabic words; it is rather a general knowledge of such of the main developments of biological science as are of importance, either practical or cultural, in the citizenship of the civilised State.

Each of the two main branches, then, of science the physical and the biological—has its own rôle to play in elementary education, and it is of the greatest importance to realise this. It is of equal importance to realise what is wanted from each branch. In neither case is it masses of complicated detail. In the case of physical science, it is the careful repetition of observation and experiment in their simplest forms and the recording and treatment of the results arithmetically, the object being to train the young child in accuracy and rapidity of observation and reasoning. In the case of biological science, it is the acquirement of general knowledge regarding main results rather than training in the method of obtaining these results that is required by the citizen.

While the physicist may justly claim upon this showing that it is physical science that plays the more fundamental part in the educative process,

in actual practice the recognition of this claim has led to strange results, namely, on one hand the denial to biological science of any place in the school curriculum at all, and on the other, to that hypertrophy of the physical science portion of the curriculum which finds its expression in the schools undertaking courses in chemistry of a standard which is really that of the university It is a common complaint, as already noticed in NATURE, that students of science and medicine in our universities have to waste an appreciable part of their time at the university in repeating what they have already done at school The harm is much more than mere waste of time, for the quality of instruction in the average school laboratory is obviously not in a position to claim equality with that of a university department under the inspiring headship of a leader in his science

When complaint is made of the large and even preponderating part played by science in certain modern developments of our educational system, it is well to bear in mind that 'science' in this connexion is apt to mean simply physics or chemistry. As stated in Nature of Aug 13, of the candidates from grant-aided secondary schools in England in the First School Examination in the year 1926, no less than 402 per cent. offered chemistry as a subject but only 2.5 per cent. offered general science While overwhelming arguments can be adduced for science on the lines above indicated being given an important place in the school training of the average citizen, it is difficult to find any justification at all for bringing him up as a specialist in physics and chemistry completely unversed in science outside their limits.

Royal commissions are commonly regarded as the resort of harassed politicians when seeking a means of relieving some inconvenient form of public pressure But occasionally they achieve great results, and the present would seem a really appropriate time for the appointment of a strong commission to deal with the general question of national education. When such a commission is appointed it is to be hoped that its personnel will consist not of academic specialists, but rather of persons who combine recognised intellectual prestige with understanding and breadth of vision, and that its terms of reference will be as wide as possible so as to include the whole range of education from the elementary school to the university. The selection of the personnel should provide a means of securing that its activities would be confined to big things and not wander away into the desert of detail.

# Réaumur and his Work on Ants.

The Natural History of Ants from an Unpublished Manuscript in the Archives of the Academy of Sciences of Paris By René Antoine Ferchault de Réaumur. Translated and annotated by Prof. W. M Wheeler. Pp xvii + 280 + 4 plates. (New York and London. Alfred A. Knopf, 1926.) 25s

DENÉ ANTOINE FERCHAULT, Seigneur de Réaumur, was born at La Rochelle in 1683. After a short course of training in the law, he devoted himself to the serious study of mathematics, and at the age of twenty-four years was admitted a member of the Academy of Sciences. His life for the next fifty years was one of constant application to scientific research in the departments of physics, metallurgy, crystallography, and meteorology, as well as natural history. His work included experiments on torsion, on the ductility of metals, on the manufacture of steel, of tin-plate, and of porcelain. In physics he investigated the temperature of mixtures, and devised the scale which long remained the prevailing system of thermometric graduation on the Continent.

Réaumur's chief interest, however, lay in natural history, and his achievements both in observation and experiment were truly remarkable. He was the first to describe the ambulacra of starfishes, and to him were due the first systematic observations on the reproduction of cast limbs in the Crustacea, which he attributed to the presence of minute living particles, called by him petits œufs. The physiology of digestion engaged his attention, and some well-devised experiments enabled him to demonstrate the action of gastric juice upon proteid foodstuffs. But the object towards which his efforts were mainly directed was the study of the instincts, life-history, and general behaviour of insects; and it is on his writings in this department of research that his reputation among present naturalists chiefly rests.

The volume before us contains a careful transcription of the hitherto unpublished "Histoire des fourmis," which was apparently intended to form part of the seventh volume of Réaumur's "Mémoires pour servir à l'histoire des insectes," of which six volumes were issued between 1734 and 1742. To the original text, Prof. W. M. Wheeler has added an excellent translation and a series of valuable annotations. In these he has performed the useful task of giving at length many passages of other authors to which Réaumur refers, and the still more meritorious office of interpreting and

correcting Réaumur's statements in the light of present knowledge. It may perhaps be remarked in passing that it would be well if some competent person were to render a like service to the biological It was searcely to be extreatises of Aristotle pected that the pioneer work even of so shrewd and capable an observer as Réaumur should be free from errors of faulty inference, arising partly from limited opportunities and partly from imperfection of the optical means at his disposal He was the first to observe the fact that ants ascend trees for the purpose of feeding on exudations furnished by aphides and scale-insects, but it is not surprising that his account contains one or two inaccuracies. So, too, the microscopic technique of his day did not enable him to recognise that the workers were not really sexless, but were normally sterile females.

To Réaumur is due what is perhaps the earliest experiment in phototropism. He also was probably the first to observe recently fecundated females in the act of founding colonies. Gould, to whom the original observation of this proceeding is commonly attributed, did not publish his account until 1747, whereas Réaumur's must have been written (though not published) before 1743. The same remark applies to Réaumur's discovery of the feeding of larvæ by liquid disgorged by the workers; also described by Gould in 1747. Another of Réaumur's records contains the first account of mutual feeding among ants; and yet another, only recently verified, deals with the facilities provided by the workers for the larvæ in the act of spinning their cocoons. Experiments were started by him with the object of ascertaining whether ants would tolerate the presence of larvæ belonging to an alien These experiments, however, apcommunity. parently did not extend beyond the limits of the same species.

In all Réaumur's work, painstaking and thorough as it was, it is curious to recognise that systematic zoology made little or no appeal to him. His interest lay almost entirely in observation and experiment on insect behaviour, scarcely at all in insect morphology. Classification in his day was in its infancy, and we need not be surprised that he draws no distinction between ants and termites. But when we find him saying, "It seems to me that the many hundreds and hundreds of species of gnats and very small moths which exhibit nothing more remarkable than a few slight differences in the form of the wings or the legs, or varieties of coloration or of different patterns of the same colours, may be left confounded with one

another," we cannot but realise how widely his point of view differs from that of the modern zoologist.

Still more startling, as Prof. Wheeler says, "is his conception of the insects as a natural class, since, like other naturalists of his day, he not only included in it the worms, polyps, mollusks, arachnids, myriopods, and crustaceans, but also the reptiles." The limit is perhaps reached in his remark. 'The crocodile is certainly a fierce insect, but I am not in the least disturbed about calling it one." Laxity of this kind was not likely to commend itself to Cuvier, in whose article in the "Biographie universelle," mainly eulogistic, it is possible to discern a certain coolness in regard to Réaumur's merits as a naturalist Not much sympathy was to be expected between men whose temperaments and methods differed so widely as those of Réaumur and Buffon, and as a matter of There is, however, no sufficient fact none existed reason for supposing that the non-publication of the concluding volumes of the "Mémoires" was due to an intrigue set going by Réaumur's formidable rival.

Prof. Wheeler's book is well printed and well produced. It will be of great value to all those who are interested in the historical stages of our acquaintance with the habits and life-history of the remarkable insects of which it treats

F. A. D.

## Metalliferous Mining Methods.

The Working of Unstratified Mineral Deposits. By George J. Young. With a Chapter on The Hæmatite Ores of Cumberland and Furness, by T. S. Durham. (Benn's Mining Series.) Pp. 466+12 plates. (London: Ernest Benn, Ltd., 1927.) 42s. net

THIS volume forms the second of a series of works dealing with the various phases of mining which is being produced by Messrs. Benn, Ltd., under the general editorship of Prof. Henry Louis. To quote the editor's introduction, "There is probably no industry that depends upon so great a variety of other arts and that involves so many branches of science as does mining, nor one that includes such a complexity of operations." The most important of all the phases is the winning and working, or extraction of the deposit.

Mineral deposits, broadly speaking, can be divided into two divisions, namely, unstratified and stratified, the former being essentially metalliferous, and the latter largely coal and stratified ironstone and such deposits as the Rand goldfield.

The subject of extraction is so wide and varied that the editor of the series has wisely decided to treat it in two volumes and this volume deals essentially with the working of unstratified deposits. The remaining volumes of the series are being written by British mining engineers, but the author of this particular volume is a well-known American. As the United States of America is the largest metal-mining country in the world at the present time, the choice of the author is a wise one, as he has been able to draw upon the accumulated knowledge of his own country to furnish examples and descriptions of the methods of working every conceivable type of deposit. The book is therefore very largely a manual of American practice There is, in addition, at the end of the book, a short chapter by T. S. Durham describing the methods of working the hæmatite ores of Cumberland and Furness

The book can be divided into four parts, namely, a general consideration of mining methods and mineral deposits, followed by the three main chapters dealing with narrow, wide, and large ore bodies respectively

The chapter on ore deposits refrains from any comments on the genesis of such deposits, but discusses generally their practical features, such as their varying shape, size, depth, physical characteristics, the effect of the enclosing walls and the behaviour of the surrounding earth masses during and after excavation

In many deposits the line of demarcation between the suitability of open cast and underground methods of working is indefinite. It is quite impossible to lay down any law on the subject, and no attempt is made to do so

The chapter on mining methods is good and comprises two main features; first, a description of the various forms of supports used in underground mining and the conditions under which they may be used advantageously or must of necessity be adopted. The merits of timber supports, the permanent filling of the excavation with waste rock, and the use of broken ore as a temporary support are fully discussed. The second portion of the chapter deals with the many variations of three simple methods of working which are characterised by the line of advance of the working faces, namely, upwards, downwards, or horizontally. One of these three methods, combined with the materials used for supporting the excavation, constitutes the system of working employed to excavate any given deposit.

One of the particular features of this book is the

attention paid to the methods employed for working large low-grade deposits upon which the modern mining industry has largely to rely owing to the small comparatively rich deposits of the nineteenth century becoming exhausted. This necessitates the handling of large quantities of material, and many of the methods of working described in detail have been devised for this purpose. When dealing with large quantities small economies make all the difference between profit and loss, and attention is directed to points where saving can be effected.

The selection of a mining method is based primarily on its suitability for the physical conditions of the ore body and upon the cost comparison of different methods that may be applicable under the given conditions. Costs are expressed in terms of labour and materials, sometimes graphically and sometimes in tabulated form. This will enable engineers in other parts of the world to compare the working costs of their own mines with those given by the author for alternative methods.

In the three chapters dealing specifically with ore bodies of various sizes—a narrow size being one less than 12 feet thick, while the subdivision of the remainder into wide and large ore bodies allows for a very elastic treatment—the author discusses the characteristics of such deposits and then proceeds to show how variations in their characteristics affect the method of working. This entails primarily a general statement of the principles involved and is followed up by detailed descriptions of the application of these principles. Many examples of successful application are given, and it is in these chapters that the author's wide experience of American metalliferous mines is displayed at its best.

In mining unstratified deposits, no general law as to the method of working to be adopted can be laid down. Each individual case has to be decided on its merits, and the decision is further complicated by the uncertainty which always exists as to the size, shape, and future value of the deposit. Knowing this, stress is laid upon the necessity for development work and the provision of ample 'ore in sight.' The numerical value of the 'development ratio' is not, however, fully discussed.

When it is realised that metal mines are being worked at deeper levels every year, and that one of the determining factors in the successful operation of deep, and therefore hot, mines is the comfort of the workers, more space might have been allotted to the necessity for an ample flow of cool dry air round the working faces. The provision of adequate ventilation is intimately bound up with the method of working employed.

The book is bulky, being printed on thick paper, and, at the same time, loosely bound. As it should find a place in the library of all metalliferous mining engineers, whose sphere of work is often far from modern means of transport, it might well have been compressed into a smaller and stronger volume. The print is large and easy to read, and the illustrations, many of which have been specially prepared for this volume, are excellent. It is the most complete work dealing with the mining of unstratified minerals yet published.

# The Egyptian God of Medicine.

Imhotep: the Vizier and Physician of King Zoser and afterwards the Egyptian God of Medicine
By Dr. Jamieson B. Hurry. Pp. xvi + 118 + 13 plates. (London: Oxford University Press, 1926.) 7s. 6d. net.

TITHE author of this volume, himself a doctor of medicine, is inclined to chide the medical profession for neglecting its true patron saint, who was in practice more than two thousand years before either Hippocrates or Galen - It is doubtless partly to help Imhotep to his own that Dr. Hurry has written the present book. It is, as it could not but be, based on Sethe's masterly memoir on the same subject written twenty-four years ago. There is not much to be added to this Sethe's work does not age rapidly -but what there is Dr Hurry has found and added The most striking additions are the Nechautis Papyrus from Oxy rhynchus, which, if its story could be trusted, would put back the full deification of Imhotep by 2000 years, Gauthier's article on the Imhotep festival, and Milne's on the graffiti in the Sanatorium of Der el-Bahrî. We are at a loss, however, to understand why he has completely ignored the account of King Zoser given by both the epitomisers of Manetho the Egyptian historian, which, if Sethe's elever and convincing conjecture be correct, is a description of Imhotep himself.

Imhotep was an Egyptian Leonardo da Vinciarchitect, writer, and physician in one. Though the discoveries at Saqqara during the last two winters have shown that his achievements in building must have been very considerable, it is as a doctor that he survived in the memory of the Egyptians. How soon he became what Dr. Hurry

describes as a "medical demigod" we cannot say. probably shortly after his death. In this stage he remained, if we hesitate to accept the evidence of the papyrus mentioned above, until the Persian period, about 525 BC, when he first appears with the full attributes of a god. These developments in his status Dr. Hurry describes very clearly and with due regard for the value of various types of evidence. Both here and in the all too short chapter on Egyptian medicine, he shows a happy ability to clothe an ingenious conceit in a neat garb, and this makes his book very readable

A few small points, mostly lying outside the main line of the argument, call for remark Hurry has been a little unfortunate in his authorities on some points connected with Egyptian belief Thus the Liturgy of the Funerary Offerings did not aim at changing the offerings into "a divine and spiritual food, which was partaken of by the souls of the departed" (p 13). One of the most certain things about Egyptian belief is that the dead were envisaged as still physically living, though perhaps in a slightly different sense from that in which they had lived here Hence the need for mummification to preserve the body, and the terror lest this should be destroyed. This physical body needed physical food, and that is precisely what was given to it. A similar error appears on p 64, where Dr Hurry states that what persists after death is the ka or double, and that it is this 'part' of a man which needs the nourishment. What eats the food is in reality no ku, but the dead man himself. For such mistakes the Egyptologists and not Dr. Hurry are to blame. On p 15 we read that the Kheri-heb priest was "by the common people . . regarded as the mediator between the King and the unseen powers of the universe" Such an idea is totally un-Egyptian. In Egyptian religion the king is in theory the only priest, and the whole funerary ritual is performed by him as the incarnation of Horus for the dead person conceived as Horus's dead father Osiris There can be no mediator between the king and the gods or the dead.

On p 77 we find the curious remark, "More complicated operations were performed on the domestic animals than on man." This is a most interesting example of how errors arise. In the tale of King Khufu and the magician Dedi (Papyrus Westcar) the king wishes to see Dedi perform his vaunted trick of cutting off a head and fastening it on again, and commands a prisoner to be brought for this purpose. The following sentence is obscure, but it would seem

that Dedi suggests making his experiment not on a human being but on one of the domestic animals. This I take to be the origin of Dr. Hurry's statement: at least I can find no other.

In Appendix B, on the name Imhotep, the author has been dogged by ill luck. The transliteration IJ-m-htp is a purely German form, the German J representing our consonantal J Read therefore Iy-m-htp. Secondly, the verb htp means not 'to satisfy,' but, intransitively, 'to be content' Thirdly, there is no 'particle' m meaning 'as' or 'm the guise of'; this m is precisely the preposition meaning literally 'in' of which Dr Hurry has just been speaking. Fourthly, though it is not grammatically impossible that the element IJ should be the imperative, yet the rarrity of this form and the absence of variants of the name showing the much more common form Mi make it unlikely.

In conclusion, I hope that Dr Hurry's conception of the high standard of Egyptian hygiene is a true one, but I cannot help feeling that if he had excavated, as I have, an Egyptian city, he would have misgivings

T. E. Peet.

# The Vegetation of the British Empire.

Aims and Methods in the Study of Vegetation.
Edited by Prof. A. G. Tansley and Dr. T. F
Chipp. (Published by the British Empire
Vegetation Committee) Pp xvi + 383 + 19
plates. (London: The Crown Agents for the
Colonies, 1926) 12s 6d

WING to the foresight and mutiative of Sir Joseph Hooker, we now possess published floras of many of the British colonies, but such floristic data is only the pioneer work which should form the basis for further research The time has now come when the investigation of the vegetation of the Empire can be profitably undertaken, and indeed urgently demands attention. Quite apart from the value of such knowledge for its own sake, an ecological survey of the Empire is of paramount importance for its further economic development. To exploit the natural vegetation of any region to the best advantage, we require to know much not only with respect to its existing composition and structure, but also its potentialities under the more or less artificial conditions imposed by man.

The British Empire Vegetation Committee appointed by the Imperial Botanical Conference in 1924 in furtherance of these aims has published the volume before us. The first section comprises a brief account of the nature of plant communities,

the method of their investigation and the factors of the habitat, whilst the remainder is in the nature of a symposium of essays by different authors which, though often overlapping, have their chief value in the diverse viewpoints which they present, with consequent diversities of technique and emphasis. Moreover, many useful practical hints are furnished for the investigation of the respective areas dealt with. Of especial interest are the sections on the ecology of fungi and lichens by Mr. Ramsbottom.

Perusal of these pages emphasises the need in vegetation studies for accurate empirical descriptions unbiassed by any theory which attempts to fit the communities observed into a hypothetical succession series or to find their equivalence with communities in other areas which have been investigated on different lines Too rigid a uniformity is much to be deprecated, but if the attempts at classification of plant communities are to be rescued from their present somewhat chaotic condition, it is essential that the various aspects of the community and habitat alike should be studied. At present we know much concerning the soil conditions in the communities of one region, of the putative successions in another, of the physiognomy or the biological relations in a third. Each of these lines of investigation has, indeed, at one time or another, served as the basis of a more or less exclusive classification, but if the pages of this volume serve no other purpose than to bring about a wider and more uniform basis of investigation of the communities within the Empire, the task of the synecologist of the future will be appreciably diminished.

How important, from the economic viewpoint, is a knowledge of the plant communities and the successions of any area, is shown by the changes which fire protection has wrought in India, to which Prof. Troup directs attention in his suggestive survey of Indian forest vegetation. Such protection has not only resulted in replacement of grassland by forest, but has also produced profound changes in the composition of the forest itself. The widespread effect of the shifting cultivation practised in the tropics is emphasised by several of the contributors. To this cause both Prof Troup and Dr. Stamp attribute many of the grassland areas and bamboo thickets in the forest regions of India and Burma, whilst the same factor is held by Dr. Chipp as initially responsible for the forest retreat in West Africa. Prof. Bews shows how a study of the successions in the grass communities of South Africa has both explained

the conflicting views respecting the value of burning and supplied the criteria for ensuring the appropriate and successful use of this method.

It cannot, however, be too strongly urged that if the fullest use is to be made of ecological methods for the solution of economic problems, it is essential that the study of vegetation should be accompanied by a parallel study of the animal ecology. The valuable conclusions arrived at by Dr. Cockayne in his studies of palatability in the tussock grasslands of New Zealand, have shown how profound an effect the selective action of grazing animals may produce, whilst the thickets of Zizyphus anophia in the Central Provinces or the spread of Opuntia incrimis in Australia serve but to show that man is not alone in upsetting the balance of Nature to the detriment of his environment.

E. J. Salisbury.

#### Our Bookshelf.

The Music of the Spheres. a Nature Lover's Astronomy. By Florence Armstrong Grondal. Pp. xiii+334 (24 plates). (New York. The Macmillan Co., 1927.) 21s. net.

THE author has collected a large number of myths and poetical references associated with the heavenly bodies, and has woven them into a discursive description of the stars in their constellations and of the members of the solar system. The first ten chapters are replete with legends by which the more spectacular stellar objects (bright stars, double stars, clusters, and nebulæ) may be remembered. The remaining seven chapters are descriptive of the sun and its satellite members of the solar system, an interesting perspective of the geological processes through which our planet has passed is given in one of these chapters. Simple language and illustrations are employed generally, but a few terms such as 'spectroscope,' 'seconds' (of arc) might have been explained. A brief description of a refracting and a reflecting telescope is left to the final paragraphs, which contrast unfavourably with the opening sentences of the book. Occasionally accuracy of statement is sacrificed for rhetoric—the sun's corona is described as 'flaming,' and prominences are spoken of as 'burning gases' The sentences on p 12 concerning the measurement of the sun's diameter and those of only four or five of the stars convey a wrong impression of astronomical measurement. A mis-statement appears on p. 74, where the distance of the Andromeda nebula is given as 36,000 light years instead of one million Incidentally, the quotation on p. 76 is from Keats, not Longfellow.

With slight exception, the reproductions of photographs are admirable and make a very attractive feature of the book: a few star charts (coloured for preference) showing the whole heavens would, however, have assisted the reader

in linking up the many constellation diagrams, a few of which appear somewhat redundant. Finally, it should be remarked that the volume is essentially a gift-book, with its large print, heavy paper, and choice reproductions, and it will be unfortunate if its cost should deter any one from possessing a copy or placing one in the hands of a friend

Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof. Dr. Emil Abderhalden Lieferung 220 Abt 11 Chemische, physikalische und physikalisch-chemische Methoden zur Untersuchung des Bodens und der Pflanze, Teil 3, Heft 5. Ernahrung und Stoffwechsel der Pflanzen. Methoden der mikrobiologischen Bodenforschung Von Selman A Waksman Pp. 715-864. (Berlin und Wien: Urban und Schwarzenberg, 1927) 7 20 gold marks.

The study of the activities of soil micro-organisms is of comparatively recent origin, and consequently the methods employed for such researches are not well known, and in many cases have not attained the degree of standardisation necessary for comparative investigations. This is particularly the case with regard to the numerous methods employed for counting the numbers of soil bacteria, protozoa, fungi, or algae, and for estimating the degree of activity of such members of the soil population The present part of Abderhalden's "Handbuch" should prove exceedingly useful to soil investigators. S. A. Waksman has acted as general editor and has contributed the mycology and bacteriology sections, with the exception of that on cellulose decomposition, which is written by Chr. Barthel of The technique used in the study of Stockholm soil algae and protozoa is described by B M Bristol-Roach and D. W. Cutler respectively.

With a subject growing so rapidly as soil microbiology, any book is to a certain extent out-of-date before it is published, and though doubtless certain sections of the present part of "Abderhalden" would be slightly altered if rewritten, yet it can be safely recommended as the most up-to-date work on the

Grundriss der Kriminalbiologie: Werden und Wesen der Personlichkeit des Taters nach Untersuchur\_n an Straflingen. Von Prof. Dr. Adolf Lens. Pp. vii + 252. (Wien . Julius Springer, 1927.) 15 gold marks

DR LENZ, as director of the University Criminological Institute of Graz, is well fitted to describe to us the influence of the personality on criminals, and in this book he does this in an extremely able manner. His case material consists of criminals from the prison at Graz and the Petty Assize prisons in Vienna and Graz. He regards crime as the resultant of the interaction of personality and its environment. In the personality he includes the physical structure as well as the psychical, and in this is following much the same lines as Kretchmer does in his well-known "Korperbau und Charakter."

The author divides his book into four parts. The first part deals with his method of investigation and

the nature and problems of criminal biology The second part is concerned with the nature and development of personality, the importance of symbolism and the reaction of the personality to its environment. In the third part, the actual crime and its relation to the personality and its environment are considered. The fourth part deals with the sensory, intellectual, and volitional tendencies, the structure of the ego, and the relation of crime to the sex and herd instincts.

Graphit: Charakterıstık, Erzeugung, Verarbeitung und Verwendung Von Dr Eugen Ryschkewitsch. (Chemie und Technik der Gegenwart, Band 7.) Pp xii+323 (Leipzig S. Hirzel, 1926.) 14 50 gold marks

This monograph is an interesting and well-printed volume, commendable for good arrangement of the subject matter. Though the author admits that his sources of reference are limited, he offers much up-to-date information, giving considerable attention to a detailed description of the chemical, physical, crystallographic, and mineralogical characteristics of graphite; this is invaluable alike to student, manufacturer, and consumer. The dressing and refining of the material are dealt with m a more cursory manner than is usual m books on this subject, but the writer nevertheless indicates the fundamental principles of preparation in a lucid manner. There are also some interesting chapters on the distribution of the raw material and its origin in Nature, on the artificial formation of graphite, on industrial applications, and on commercial statistics; in the last, the author's criticism of certain figures published by the Imperial Mineral Resources Bureau is noteworthy, as it indicates that he does not quote even supposedly reputable information without duly pondering on its value. The book may be considered an asset to a scientific or technological library.

The Nature of Man. By Dr. G. A. Dorsey. Pp. viii + 104. (London: Harper and Bros., 1927.) 3s. 6d. net.

In this little book Dr. Dorsey has in mind the practical and immediate application of the scientific study of man. "Everything said in this book may be taken personally," he says, in his opening chapter, and his concluding words are: "Nothing is known of God's will; enough is known of Nature to point the way Man must travel if he is to survive and the goal he must desire to make the most of his nature." Dr Dorsey's method of attacking the problem is by an exposition of man's nature and activities as an individual and as a member of family and other social groups upon a purely mechanistic basis. The mind, the soul, the group mind, the herd instinct, in short, the whole of the material of the psychologist, as well as his terminology, disappear in favour of what science 'knows'-visceral behaviour, genetic behaviour, somatic behaviour, social behaviour, and cultural behaviour. Dr. Dorsey's little book is an aid to clear thinking, even if his readers will not be prepared to go the whole way with him.

#### Structure in Surfaces of Liquids.

Mr. Hatschek, in his interesting article in Nature of June 11, p. 857, has shown that colloidal solutions and even the simplest suspensions of solid particles in liquids exhibit a property which is absent from all true liquids; namely, residual rigidity, or at least a coefficient of viscosity that depends upon the rate of shear. He has advanced no explanation of this remarkable result, which would, however, appear to be just one manifestation of a general property of all

surfaces involving liquids

In an address delivered by me before the Mid-West Regional Meeting of the American Chemical Society at Madison in June 1926 (since communicated for publication in the Journal of the American Chemical Society), absolute measurements of the adsorption of such substances as p-toludine in the surfaces of their aqueous solutions were adduced, which made it eyident that the excess of dissolved substance in the surface is several times greater than that which can be close-packed as a monomolecular film resting upon the surface. This demonstrates that the surface of a liquid possesses a depth which is considerable as compared with the diameter of a molecule, and the obvious inference was drawn that chains of oriented molecules of dissolved substance extend inwards into the solution until they are broken up through thermal The usual structure of the surface even of pure liquids would appear to be a single complete layer of oriented molecules with numerous unstable chains of oriented molecules extending therefrom into the liquid. It is evident that this hypothesis predicts a quasi-rigidity in the neighbourhood of all surfaces bounding a liquid, and suffices to explain the facts mentioned by Mr. Hatschek.

Evidence for the truth of this hypothesis is to be found in many fields. For example, in numerous experiments upon adhesion and adhesives, whether with pure substances or mixtures, liquid or solidified, we have always found "the thinner the film, the stronger the joint," the effect increasing most rapidly when the thickness of the layer under investigation is reduced to the order of a millionth of an inch. It likewise serves to explain the considerable effective range of molecular attraction without involving more than direct action of molecules upon others with which they are immediately in contact. Another illustration is given by the effect of finely divided fillers' such as carbon upon the strength and resiliency of rubber tyres or by the effect of oil upon troubled water. It is gratifying to find that recently Sir William Hardy (Jour. Gen. Physiol., 8, 641; 1927) has come to similar conclusions from experiments on

lubrication

In an article in the Journal of Physical Chemistry (30, 239-247; 1926), I put forward as a general explanation of the high apparent viscosity of many colloidal solutions the tendency of colloidal particles to aggregate into larger secondary structures ramifying through or partially enclosing large tracts of solution that are thereby effectively immobilised Mr. Hatschek (J. Phys. Chem., 31, 383-392; 1927) has attacked this quite general hypothesis, which includes many special cases, in favour of one single form of it. It seems preferable to retain the more general and inclusive

view. Whatever form of ramitying aggregate is present in a colloidal solution, the surfaces of the colloidal particles will be surrounded by chains of oriented or linked molecules extending towards each other and thereby imparting far greater effective rigidity and apparent viscosity than could be produced by the colloidal particles or aggregates themselves.

JAMES W MCBAIN.

Department of Chemistry, Stantord University, California, Aug. 11

#### The Production of Sound by Heat.

THE 'singing tube' has been the subject of a number of short sketches by me in American scientific journals. There is one form of it, however, that was exhibited at the Cavendish Laboratory in February last that has never been published, and a brief description of the tube in general and of this special form may be of interest to the readers of Nyruke.

The singing tube came to my notice quite by accident while blowing a mercury vapour trap for

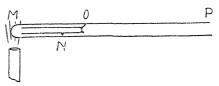

Fig. 1.

high vacuum work. Two reasons may be assigned as to why it was not discovered long before by research workers doing their own glass-blowing. They are: (a) the trap was blown of Pyrex glass (Monax would have answered quite as well), which permitted of more intense heating than soda glass, and (b) the sequence of operations in blowing happened to be such that it revealed this particular phenomenon. It was soon found that the tube could be given the more compact form shown in Fig. 1, drawn approximately to scale. The inner tube (a test tube) is held in the position shown by three legs fused to the outer wall, and to secure it against mechanical breakage three small supporting ribs (only one is shown) are equally spaced at N. Roughly, the area of the open end of the inner tube should be equal to the annular area between it and the outer tube. The outer tube is closed at M. When the tube is cool, place the tip M in a Bunsen burner flame (as shown in Fig. 1) and in a few moments the tube will emit, at its open end P, a tone of remarkable purity and loudness. The pitch depends

Fig. 2

on the length of the tube from O to M to P, this length corresponding approximately to one quarter of the wave-length of the tone emitted. Extensions attached at P lower the pitch. Two similar tubes simultaneously heated will sound beats. Many additional beautiful and striking experiments may be performed.

The special form of the tube alluded to above is made much longer, and in addition is closed it P, as shown in Fig. 2. On holding this tube  $\mathfrak{M}$  the hands and heating the tip M in a Bunsen flame the operator will feel the tube begin trembling, then violently, and yet no sound is heard. The whole

performance is uneamly and one is in danger of dropping the tube. The vibration of the air within will continue for some moments after the tube is removed from the flame. These vibrations may be made audible by placing the closed end P against a resonating body—one's head, a tin can, a light table, or against a wooden blackboard

The intensity of the tone emitted by these tubes is dependent upon the temperature difference that is established between the tip M and the rest of the tube. The pitch, as previously stated, is determined by the dimensions and is little affected by a change in temperature. It may be of interest to remark that when the body of the tube NOP, Fig. 1, is at room temperature, the tube will begin to sing when the tip is heated to about  $400^{\circ}$  C. When NOP is cooled to liquid air temperature, the tube will sing when the tip M is maintained at room temperature, which makes the temperature difference in this

which makes the temperature difference in this instance about 200° (' By extrapolation it was found that the temperature difference required it it were possible to cool NOP to absolute zero would be 80° Kelvin. The pitch of the tone emitted in each of the above examples is correspondingly lowered.

The tollowing physical explanation, in collaboration with Dr. Jakob Kunz, University of Illinois, is offered.

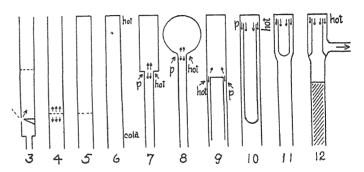

In the organ pipe, energy is supplied by a stream of an which encourages the vibrations in a one-sided way, so that the vibrating column receives an inpulse each time when the air moves upward towards the node in the niddle of the pipe, Fig. 3, and receives no involves in the converte

and receives no impulse in the opposite motion. It looks as if a pendulum were kept in oscillation by receiving at one end of its path an impulse always in the same direction. If we were to apply the momentum of the air-jet at the centre of the tube, vibrations of the column would be discouraged.

We can communicate momentum to a vertical open-air column by heating it. If we heat the air in the tube in Fig. 4 by a wire net placed in the lower half of the tube, we shall obtain a uniform current of air upwards. If the air is vibrating, then as it is moving inward its vibration is increased by the momentum of the upward stream of air, but not increased by moving downward. When we place the hot were net in the middle of the tube it will tend to increase the pressure of the gas when it is a minimum, i.e it will discourage oscillations. The same will happen when we place the net above the middle. In order to encourage oscillations we have to add momentum in a position and at a moment such that the pressure in the node increases more than it would do on account of the oscillations alone If we put the hot wire net at the lower end of the tube, i.e. in a loop, the effect will be very small, or zero. The transfer of lifat will depend upon the temperature of the air in contact with the wire net, being greatest when the temperature is lowest. But the temperature in the loop at the lower end does not vary; therefore, the transfer of heat in this position of the gauze does not give rise to oscillations. It tends only to raise the temperature of the gas uniformly. Heat must therefore be applied between a loop and a node.

If we cover the upper end of the tube, Fig. 5, with the hot net in the most favourable position, the sound ceases, and if we heat by means of a Bunsen burner the outside at the top, as in Fig. 6, we get no sound. This was considered by Rayleigh as possible ("Theory of Sound," vol. 2, p. 231). But if we change the cross-section of the tube, as in Fig. 7, and heat at p, then the tube will emit a sound. The pressure in the

upper half of the tube will increase, partly because the air is heated, partly because of the condensations of the air in the node on the top The air will expand, and now the expansion in the narrow neck is aided by the air being heated by the wall. Here the oscillations are encouraged because each time when the air is expanding by the oscillation the expansion is increased by the heat. In each cycle the vibrating particle receives one push in the right direction. It is this one-sidedness of the action which encourages the oscillations. Moreover, as the heat here has the tendency to increase the pressure near the node, the oscillations will start very readily. A slight modification of this experiment is the glassblower's bulb, Fig. 8, which emits a sound when heated around the neck, p. Instead of making the lower part of the tube narrower, as in Fig. 7, we might proceed as in Fig. 9, where the annular area takes the place of the narrow tube in Fig. 8. A modification of this tube is

the tube of Fig. 10, which will sound when heated at p and is much more sensitive. It is evident from the explanation that this tube will not sing when the lower end of the inner tube is open, because the one-sidedness of the action is destroyed. Slight modifications of Fig. 10 are the tubes represented in Figs 11 and 12. If we place a hot wire net inside the tubes of Figs 7, 8, 9, 10, 11, 12, where the hot flame was outside, the tubes will produce a sound. In all cases, in the organ pipe, in Rijke's experiment (Fig 4), and in the tubes in Figs. 7-12, the oscillations of a column of air are maintained by a one-sided addition of momentum at the right moment and in the right place.

These experiments belong to a large variety of phenomena in which a direct motion is transferred into a periodic motion, or, electrically speaking, where direct current is transformed into alternating current.

Chas. T. Knipp.

Cavendish Laboratory, Cambridge, July 12.

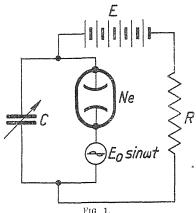

#### Frequency Demultiplication.

It is a well-known fact that when a sinusoidal E.M.F (of the form  $E_0 \sin \omega t$ ) is available, it is a relatively simple matter to design an electrical system such that alternating currents or potential differences will occur in the system, having a frequency which is a whole multiple of the applied E.M.F., e.g.  $2\omega$ ,  $3\omega$ , etc. For example, when the E.M.F.  $E_0 \sin \omega t$  is applied to a diode-rectifier, the current in the anode circuit will include a component of double frequency, i.e.  $2\omega$ . This is therefore one method of frequency multiplication. Several other methods could easily be mentioned.

Now we found it is also possible to design an electrical system such that when the above-mentioned

E.M.F.,  $E_0 \operatorname{sm} \omega t$ , is applied to it, currents and potential differences occur in the system the frequencies of which are whole submultiples of the frequency of the applied E M F.,  $eg=\omega/2,\;\omega/3,\;\omega/4$  up to  $\bar{\omega}/40$ .

To this end one can make use of the remarkable synchronising properties of relaxation-oscillations,

i e. oscillations the time period of which is determined by the approximate expression  $T = \pi/2 CR$ , a relaxation time (Balth, van der Pol, "On Relaxation Oscillations," Phil. Mag., p. 978, 1926; also Zeutschr. f. hochfreq. Technik, 29, 114; 1927).

Let Ne in Fig. 1 represent a neon glow lamp.

R a resistance of the order of a few megohins, C a

variable condenser of approximately maximum 3500 cm. capacity and E a battery of say 200 volts. In the absence of the E.M.F.  $E_0 \sin \omega t$ , this system will oscillate with a time period T = a C R where a is a number of the order unity. With the E.M.F.  $E_0 \sin \omega t$  present, where  $E_0$  may be of the order of 10 volts (considerably lower voltages also give the same result) it is found that the system is only capable of oscillating with discrete frequencies, these being determined by whole submultiples of the applied frequency. For example, with  $E_0 = 0$ , give Ua small value such that the natural relaxation frequency of the system is 1000 periods per second. Next apply the alternating voltage  $E_0 \sin \omega t$ , where  $\omega$  may be made  $2 \pi \times 1000 \text{ sec.}^{-1}$ , then

the system will go on oscillating with a frequency 1000 sec.-1. When now the applied  $E_0 \sin \omega t$  is left as before but C is gradually mcreased to a much greater value, it will be found that the system continues to oscillate with a frequency 1000 sec. 1. If C is next increased still further, the frequency of the oscillations in the system (as detected, for example, with a telephone coupled loosely in some way to the system) suddenly drops to 1000/2 sec.-1, to maintain this value over a certain range of the capacity value. If C is increased still more, the frequency suddenly jumps to 1000/3 sec.-1, and so on

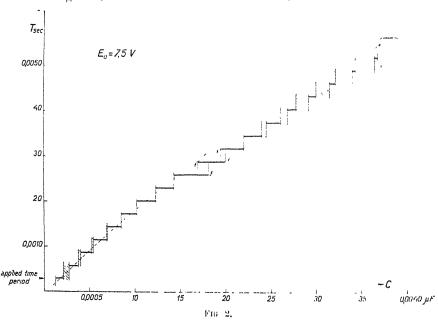

up to 1000/40 sec.<sup>-1</sup> In some recent experiments it was found possible to obtain a frequency demultiplication up to the ratio 1 1/200. Often an irregular noise is heard in the telephone receivers before the frequency jumps to the next lower value. However, this is a subsidiary phenomenon, the main effect being the regular frequency demultiplication. It may be noted that while the production of harmonies, as with frequency multiplication, turnishes us with tones determining the musical major scale, the phenomenon of frequency-division renders the musical minor scale audible. In fact, with a properly chosen 'fundamental' ω, the turning of the condenser in the region of the third to the sixth subharmonic strongly reminds one of the tunes of a bagpipe

In conclusion, we give in Fig. 2 the measured time periods (which are thus found to be a series of discrete subharmones) as a function of the setting of the condenser C. The dotted line in the figure gives the frequency with which the system oscillates in the absence of the applied alternating E.M.F. The shaded parts correspond to those settings of the condenser where an irregular noise is heard. In the actual experiment the resistance R was, for ease of adjustment, replaced by a diode. The experiment, however, succeeds just as well with an ohmic resistance R. Obviously the same experiment succeeds with all systems capable of producing relaxation-oscillations such as described in the papers quoted

Balth, van der Pol.

J. VAN DER MARK.

Natuurkundig Laboratorium der N. V. Philips' Gloeilampenfabrieken, Eindhoven, Aug 5.

# Movement in Fluid Dielectrics under Stress.

It has been suggested to me that I should describe briefly, for the benefit of readers of NATURE who may be interested, some experiments which I showed at the High Tension Conference in Paris a few weeks

In January last, as the result of a suggestion by Mr. G. L. Addenbrooke, who had previously investigated the phenomenon, I was able to demonstrate at the annual exhibition of the Physical Society, and

No. 3019, Vol. 1201

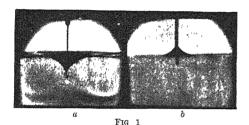

again at the Royal Institution, the rise of an oil surface under a charged sphere and the depression under a charged point. As the result of a series of further experiments, it is clear that these first two effects represent two distinct classes of phenomena, namely:

(1) The attraction of a high dielectric constant medium through a low dielectric constant medium into the strongest part of the field, and of course the repulsion of a low dielectric constant medium through one of high dielectric constant from the strong to the weak field, and

(2) the movement of a fluid dielectric under the influence of a stream of ionised air repelled from an

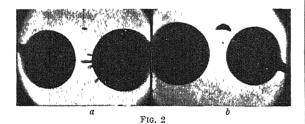

electrode

Fig. 1,  $\alpha$ , shows the cratering of an oil surface under an upper needle-point at about twenty thousand volts

alternating. This is effect (2). Air bubbles enter the oil at the point of the crater, but except at quite low voltages they circulate with the mass of oil *towards* the point.

When a thin rod is employed as upper electrode with its end immersed in the oil, the application of the voltage raises the meniscus as is expected from consideration (1) above and shown in Fig. 1, b. When a certain value of the voltage is attained, however, the oil is thrown down to its 'no voltage' level accompanied by violent circulation of the oil along the surface away from the electrode. By using in turn a number of electrodes of different diameter and comparing the voltage at which the conditions changed from a steady holding of the oil to the circulation, the calculated stress in the air was found to be the same as previously published values for critical stress in air around cylindrical wires.

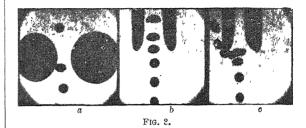

The electric wind effect is further shown by the repulsion of oil along the surface of a sheet of oiled paper standing on a flat electrode around an upper electrode in contact with the paper

Several effects arising out of consideration (1) above are shown in the remaining figures

Fig. 2, a, shows the attraction of castor oil (d c = 4 5) globules in a bath of transformer oil (d c.=21) into the strong field between two spherical electrodes, with 25 k v. difference of potential alternating, where they line up. Fig. 2, b, shows the repulsion of transformer oil globules in a bath of castor oil away from the strong field.

In Fig. 3,  $\alpha$ , bubbles of air rising through oil between charged spheres are elongated and repelled from the field, while Figs 3, b, and 3, c, show the same effects between plates. In the last figure the effect was so strong as to compel the stream of bubbles to avoid the gap entirely

The study of these movements is very much assisted by kinematograph projection, and besides

having a close bearing on the operation of cables, transformers, and other plant employing fluid dielectrics, it seems to me that they form a useful means of illustrating the principles involved

#### Climatic Changes: Their Causes and Influences.

In Nature of Aug 13 is published a review by Prof. J. W. Gregory of Dr. C E. P. Brooks's recent book, "Climate through the Ages." Referring to the remarkable evidence of a medieval deterioration of climate in Greenland, collected by the Danish expedition to Herjolfsnes, Prof. Gregory suggests that the alleged absence of ice before the thirteenth century was contradicted by the Sagas and had not been supported by any records of contemporary change of climate in Great Britain.

It is true that Sir Richard Gregory, in his presidential address to the Geographical Association in 1924, summarised a large mass of literary references dealing with British climate in historical times and failed to find any indications of such changes Nevertheless, Dr Brooks since that date has collected together a considerable body of evidence pointing to a medieval maximum of rainfall in Britain, Europe, and parts of Asia—This evidence is given in Chapters xviii, and xix of "Climate through the Ages."

A paper on "Early Water-mills in Relation to Changes in the Rainfall of East Kent," read before the Royal Meteorological Society on May 18 of this year, gives documentary records indicating that a period of heavy rainfall was drawing to a close in the latter part of the thirteenth century. The inconstant streams, or nailbournes, of Kent had been studied fairly completely by Mr. W. Whitaker (Momoir of Geol. Survey, 1908), who found that their flow depended only on the saturation level of the district. Unfortunately, Mr. Whitaker did not extend his search back beyond the fifteenth century, consequently he did not discover the extraordinary difference between the present character of these streams and that revealed by the entries in "Domesday Book" of watermills situated high up their valleys.

It would be absurd to accuse Prof. Gregory of adopting the forensic trick of passing over in silence unwelcome evidence. Probably he considers that the facts have been misinterpreted. It is not, perhaps, unreasonable to ask for his alternative explanation of these records. Quotations of the alleged critical

passages in the Sagas would also be welcomed by readers unfamiliar with this literature.

Georgie M. Meyer.

Victoria Terrace, South, Low Fell, Gateshead, Aug. 18.

I DID not refer to the two chapters mentioned as I had discussed that evidence twice previously (Geog. Jour., vol 43, 1914) and in a later paper in the Edinburgh Review. I read the two chapters with interest as they show the indefiniteness of the evidence carefully collected by Dr. Brooks, except as regards the local minor variations which are inevitable. Its inconsistency as indications of any world-wide or even widespread considerable climatic variation is shown by Mr. Meyer's case. He claims from the east Kent waternills that "a period of heavy rainfall was drawing to a close in the latter part of the thirteenth century." Dr. Brooks's table 22 (p. 345) gives a census of floods and droughts in Britain;

the maximum of floods, No. 9, was in 1051-1100, and instead of droughts in 1251-1300 being at a minimum, they were at a maximum. The figures for the seven half-centuries are as follows:

			nms an Floods	d Droughts
1001-1050			2	3
1051-1100			9	1
1101-1150			5	10
1151-1200			1	3
1201 - 1250	•		8	7
1251-1300			8	13
1301-1350		•	3	7

The thirteenth century had more recorded droughts, according to this table, than any century before the seventeenth. Mr. Meyer refers also to Asia; and according to Dr. Brooks's table 27 (p. 364) for China, the thirteenth century was less rainy than either its predecessor or suc-

cessor. The figures for rainness are: tenth century, 36; eleventh, 37; twelfth, 49; thirteenth, 36; four-teenth, 49.

I have not the Sagas to refer to, as I write from the country, but my remark regarding them was made after consultation with an authority on East Greenland who knows the Sagas well. I warmly welcome Dr. Brooks's advocacy of the dependence of glaciations and climatic variations on geographical changes and in accordance with that argument would expect that so great a change as the absence of ice from the Arctic Ocean and from the East Greenland Sea would have been attended by more marked changes in British weather than those recorded by Dr. Brooks.

J. W. Gregory.

# Fluctuations in Affective Reactions to the Odour of Caraway Oil.

During a period of two months I have arranged thirty odours in order of preference on forty occasions. Unfortunately, circumstances did not permit of this serial arrangement at regular intervals. As was to be expected, the position in the series of the very pleasant and the very unpleasant odours showed considerably less (if any) variation than the position of the relatively neutral odours. Fluctuations in the affective reactions to caraway oil claimed attention, as the median place in the series was found to be

No. 3019, Vol. 1201

higher (fourteenth) after lunch than that before (sixteenth). A similar post-praidial preference, though not so pronounced, was noticed in the ease of dill oil, which likewise contains carvone. Musk appeared to be experienced as relatively less pleasant after the meal. In the ease of camphor, rosemary oil, menthol, sassatras oil, feinel oil, and a few other observed.

A further phenomenon of some interest proved to be that a rise in the preference for caraway oil appeared to be correlated with a fall in the preference for the odour of camphor and rosemaly oil. A similar negative correlation of affective reactions, though relatively low, appeared in the case of dill oil and camphor. The accompanying diagram (Fig. 1), showing fluctuations in the median position of caraway oil and camphor on different dates, also indicates an interesting possibility of a periodic fluctuation in maffective reactions to odours. Such fluctuations have been proviously observed by me in the case of a few female subjects during menstruation, while a certain

correlation between menstruction and lumar periods has been demonstrated by Arrhenius (Skand. Arch. f. Physiol., 1898), as quoted by H. M. Fox (Proc. Roy. Soc., B. vol. 95, 1923). A ten-day periodicity in Obelia has been recorded by R. Elmhirst (Nature, Sept. 5, 1925).

In view of abundant information on the anatomical and physiological relations between the organs of smell and sex in man, facilities are required for further experimentation on a large scale, taking into consideration the various factors involved, physical, chemical, physiological, and psychological. It may be mentioned that, notwithstanding common belief, fluctuations in the degree of pleasantness or otherwise of odours, are by no means always concomitant with affective roactions due to recall of associations.

# Hot-wire Microphone and Audio-resonant Selection.

UNDER the heading "News and Views" on page 235 of NATURE for Aug. 13, reference is made to my recent paper to the Radio Society of Great Britam on the "Hot-wire Microphone and Audio-resonant Selection." The writer of the note is, I fear, too optimistic with regard to the possible applications of my paper. The invention relates to the selection and

recording of Morse telegraphic signals I think that his conclusion that there is no reason why more frequencies could not be selected in the wave bands at present employed for broadcasting misses the

Broadcasting employs a band of radio-frequency wave-lengths, and the whole range of audio-frequencies between about 26 oscillations per second to about 8000 have to be received simultaneously. Audioresonant selection, on the other hand, can be carried out on very sharply tuned radio-frequencies, and its whole object is to pick out one musical note only, and to reject all other audio-frequencies except that to which the resonator is attuned.

If this principle were applied to broadcast reception, one note only would be picked out whenever it occurred, and all the rest of the music would be

rejected

I notice also that I am credited with a statement that Sir Wm Pieece described the "Hot-wire Microphone or Thermo Telephone" to the Royal Society in 1880. In point of fact, these are two separate mstruments, and, as I pointed out in my lecture. Sir Wm Preece described the thermo-telephone in 1880, but the hot-wire microphone (or red hot wire telephone transmitter, as it was then called) was described by Prof. Geo Forbes to the Royal Society in 1887 G. G. BLAKE

#### A Vibrating Soap Jelly.

Some years ago, H. N. Holmes showed that a silicic acid jelly could be prepared which gives a musical tone on tapping. It is perhaps worth putting on record that the same phonomenon can be exhibited by a soap jelly, as Mr. P. van Campen happened to discover in this laboratory A bottle had been nearly filled with ordinary soft soap and set aside. a few months it turned out that a clear jelly had been formed. On tapping the bottle gently, it gave a very low but distinctly audible tone. It is particularly noteworthy that, whereas the silicic acid jelly is rather stiff and brittle, the soap jelly is very soft, and yields to a slight pressure of the finger.

The pitch of the tone was very low. It was a little higher after the soap had been kept at room temperature for about three months. After cooling in the ice-box, the pitch was raised again a little, as might be expected. When warmed above 25°, the jelly began to melt, but set again when cooled

and showed the phenomenon anew.

It would appear that the soap crystallises to a network of crystal fibres possessing sufficient rigidity to allow sound vibrations At a low temperature the crystals increase in number and in size at the cost of the solution contained between the network, whilst they dissolve again on warming.

I am informed that the same phenomenon has sometimes been observed in a soap factory in Holland. E. H. Buchner.

Chemical Laboratory, The University, Amsterdam.

#### Electric Charges on Omnibuses.

When light steam waggons fitted with rubber tyres were first run upon the roads, it was found desirable to provide an earthing device consisting of a short piece of chain which dangled from the vehicle to the ground in order to dissipate the electric charge which accumulated on the vehicle due to the escape of the

Under favourable weather conditions and after descending a long incline with the brakes on, the ordinary motor omnibus also becomes charged to such an extent that upon approaching the bus, just before it has stopped, a spark about 1 cm. long bridges the gap between the hand-rail and the passenger's finger.

The spark is quite attenuated, and the only sensation is a slight pin-prick, though this might be unpleasant to people who are specially sensitive to electric shocks, and it would seem that an earthing device similar to that used on steam waggons should

be provided.

That such a shock is present is known to some of the conductors, and it is usually attributed to some slight leakage from the magneto, though this is unlikely in view of the length and comparative weakness of the spark.

I have frequently noticed this effect in boarding a No. 111 bus about half-way down Crouch Hill, N.S.

#### Food-Value of Pasture Grass.

The editorial article in Nature of July 16 directs attention to the important results secured at the Cambridge School of Agriculture on the value of young pasture grass as a concentrated food for stock. In the Prairie Provinces of Canada, annual and winter annual cereals are used very widely for both hay and pasture. It may be of interest, therefore, to refer to some analyses of such material carried out at the University of Alberta.

The dry matter of young wheat plants, collected at various times in the autumns of 1921 and 1923, contained from 21 to 34 per cent of crude protein, of which about 90 per cent. was in a fluid condition in the cells. Of the total dry substance in the plants, from two-thirds to three-fourths was contained in the tissue fluids. The detailed analyses have been published in another connexion (Alta. Coll. of Agr. Research Bull. No. 1; 1924, and Jour. Agric. Sci.,

16, 522-538; 1926).
While no teeding trials were made, the analyses seem to leave no doubt that this material should rank as a high-class concentrate. R. NEWTON.

Edmonton, Alberta, Canada, Aug. 12.

#### Corrosion of Copper Pipes.

THE presence of a metal tends to inhibit the corrosion of a more electro-positive metal. On the other hand, when a metal is coated with a material to which it is electro-negative, it is well known that intense local corrosion is apt to ensue if defects arise in the coating.

Copper utensils are effectively protected by a coating of tin, the potential between copper and tin being about +0 4 volt. Tin, however, is not a suitable lining for copper water pipes. The explanation of this anomaly is that in a pipe the tin lining does not keep bright. On tarnishing it becomes more electro-positive and is ultimately electro-positive to copper. In this condition it is pernicious.

The potential between copper and the tarnished tin lining of a pipe (in water) was found to be -0.1volt. this pipe failed by local corrosion.

# The Outstanding Problems of Relativity. By Prof E T WHITTAKER, FR.S

IT was in January 1914 that Einstein (Zeits f. Math in Phys., 63, p. 215., 1914) made his great departure from the Newtonian doctrine of gravitation by abandoning the idea that the gravitational potential is scalar. The thirteen eventful years which have passed since then have seen the rapid development of the new theory, which is called General Relativity, and the confirmation by astronomers and astrophysicists of its predictions regarding the bending of light-rays by the sun and the displacement of spectral lines. At the same time a number of new problems have arisen in connexion with it, and perhaps the time has now come to review the whole situation and to indicate where there is need for further investigation.

Prof. G. F FitzGerald of Dublin long held an opinion which he expressed in 1894 in the words "Gravity is probably due to a change of structure of the ether, produced by the presence of matter" (FitzGerald's "Scientific Writings," Perhaps this is the best description of Einstein's theory that can be given in a single sentence in the language of the older physics: at any rate it indicates the three salient principles, first, that gravity is not a force acting at a distance, but an effect due to the modification of space (or, as FitzGerald would say, of the ether) in the immediate neighbourhood of the body acted on secondly, that this modification is propagated from point to point of space, being ultimately connected in a definite way with the presence of material bodies, and thirdly, that the modification is not necessarily of a scalar character. The mention of the ether would be criticised by many people to-day as something out-of-date and explicable only by the circumstance that FitzGerald was writing thirtythree years ago; but even this criticism will not be universal; for Wiechert and his followers have actually combined the old ether theory with ideas resembling Einstein's by the hypothesis that gravitational potential is an expression of what we may call the specific inductive capacity and permeability of the ether, these qualities being affected by the presence of gravitating bodies. Assuming that matter is electrical in its nature, it is inferred that matter will be attracted to places of greater dielectric constant. It seems possible that something of this sort was what FitzGerald had in mind.

Let us now consider some of the consequences of Einstein's theory. One of the first of them is that when a planet moves round a central attracting body in a nearly circular orbit, the perihelion of the orbit advances by (approximately)  $6\pi v^2/c^2$  in each revolution, where v is the planet's velocity and c is the velocity of light. This gives for the motion of the perihelion of Mercury almost exactly the amount (42" per century) which is found from observation. Another consequence is that lightrays which pass near a massive body are deflected, the bending at the sun's limb being  $1^{"\cdot75}$ . This

<sup>1</sup> From the presidential address to Section A (Mathematical and Physical Sciences) of the British Association delivered at Leeds on Sept. 5.

was confirmed observationally by the British expeditions to the eclipse of May 1919, and still more decisively by the Lick Observatory expedition to the Australian eclipse of September 1922 · the Lick observers found for the shift 1".72 + 0".11, which differs from Einstein's predicted value by much less than its estimated probable error Yet another result of general relativity is that, by the Principle of Equivalence, light which reaches us from a place of different gravitational potential (such as the sun) must exhibit a kind of Doppler effect This 'gravitational shift of the solar spectral lines' is now generally admitted to be confirmed by comparisons of wave-lengths at the centre of the sun's disc with wave-lengths from the arc in vacuo; and in 1925 the effect was observed, on a much larger scale, by W. S. Adams in the spectrum of the companion of Sirius

Besides the effects which have been verified observationally, there are many consequences of Einstein's theory which are of interest as opening up new fields or presenting new inter-relations of phenomena in astronomy and physics For example, there is a contribution to the precession of the equinoxes which, unlike ordinary precession, does not depend on the oblateness of the earth. Agam, the bending of the rays of light near a gravitating body, which has been observed in the case of the sun and the companion of Sirius, may, theoretically at any rate, be so pronounced that the ray is permanently captured by the attracting body, and describes for ever a track round and round it, which approaches spirally and asymptotically to a circle the centre of which is at the centre of gravitation. Yet another deduction is that an electrified body, or a single electron, which is at rest in a varying gravitational field, must emit radiation. Indeed, now that a definite connexion has been set up between electricity and gravitation, the whole of electromagnetic theory must be rewritten.

As a further illustration of the (as yet) unexplored possibilities of the new physics, let us consider the well-known equations for the potential of Newtonian gravitation, namely, Laplace's equation in space where there is no matter, and Poisson's equation in space where matter of density  $\rho$  is present. In general relativity, when the field is statical, these are replaced by an equation which reduces to Laplace's equation in one extreme case (when no matter or energy is present at the point) and to Poisson's equation in another extreme case (when the energy is entirely in the form of ordinary matter), but it offers an infinite variety of possibilities intermediate between the two, in which energy is present but not in the form of ordinary matter. It is possible that this equation, which evidently suggests an approach to the new wavemechanics, may play as important a part in the microphysics and astrophysics of the future as the equations of Laplace and Poisson have played in the ordinary physics of the past.

The fundamental researches of Einstein and Hilbert, with the discovery of the field equations of gravitation, were published in 1915. At that time German scientific journals did not reach Great Britain regularly, and British physicists and mathematicians were mostly occupied in one way or another with duties arising out of the Great War, so that comparatively little notice was taken of the new theory on this side of the North Sea during the first year or two of its existence, and indeed it was not until the end of the War that most of us had any opportunity of studying it In Germany, however, it was quickly realised that general relativity was one of the most profound and far-reaching contributions that had ever been made to science Its successful prediction of new phenomena of a most unexpected kind was an event of the first importance, but still more significant was its complete subversion of the foundations of physics and reconstruction of the whole subject on a new basis. From time immemorial the physicist and the pure mathematician had worked on a certain agreement as to the shares which they were respectively to take in the study of Nature. The mathematician was to come first and analyse the properties of space and time, building up the primary science of geometry, then, when the stage had thus been prepared, the physicist was to come along with the dramatis personæ—material bodies, magnets, electric charges, light, and so forth-and the play was to begin But in Einstein's revolutionary conception, the characters created the stage as they walked about on it: geometry was no longer antecedent to physics, but indissolubly fused with it into a single discipline. The properties of space, in general relativity, depend on the material bodies that are present; Euclidean geometry is deposed from its old position of priority, and from acceptance as a valid representation of space; indeed its whole spirit is declared to be alien to that of modern physics, for it attempts to set up relations between points which are at a finite distance apart, and thus is essentially an actionat-a-distance theory; and in the new world no direct relations exist at all except between elements that are contiguous to each other.

The scheme of general relativity, as put forward by Einstein in 1915, met with some criticism as regards the unsatisfactory position occupied in it by electrical phenomena. While gravitation was completely fused with metric, so that the notion of a mechanical force on ponderable bodies due to gravitation attraction was completely abolished, the notion of a mechanical force acting on electrified or magnetised bodies placed in an electric or magnetic field still persisted as in the old physics This seemed to be an imperfection, and it was felt that sooner or later everything, including electromagnetism, would be re-interpreted and represented m some way as consequences of the pure geometry of space and time In 1918, Weyl proposed to effect this by rebuilding geometry once more on a new foundation He devised a geometry more general than the Riemannian geometry which had been adopted by Einstein, instead of being specified, like the Riemannian geometry, by a single quadratic differential form, it is specified by a quadratic differential form and a linear differential form together. Thus he succeeded in exhibiting both gravitation and electricity as effects of the metric of the world

The enlargement of geometrical ideas thus achieved was soon followed by still wider extensions of the same character, due to Eddington, Schouten, Wirtinger, and others. From the point of view of the geometer, they constituted striking and valuable advances in his subject, and they seemed to offer an attractive prospect to the physicist of combining the whole of our knowledge of the material universe into a single unified theory The working out of the various possible alternative schemes for identifying these more general geometries with physics has been the chief occupation of relativists during the last nine years. Many ingenious proposals and adaptations have been published, and more than one author has triumphantly announced that at last the problem has been solved But I do not think that any of the theories can be regarded as satisfactory, and within the last year or two a note of doubt has been perceptible, Were we after all on the right track  $^{2}$  At last Einstein himself (Math Ann, 97, p. 99; 1926) has made up his mind and renounced the whole movement. The present position, then, is that the years 1918-1926 have been spent chiefly in researches which, while they have contributed greatly to the progress of geometry, have been on altogether wrong lines so far as physics is concerned; and we have now to go back to the pre-1918 position and make a fresh start, with the definite conviction that the geometry of space-time is Riemannian.

Granting, then, this fundamental understanding, we have now to inquire into the axiomatics of the theory. This part of the subject has received less attention in Great Britain than elsewhere, perhaps because of the more or less accidental circumstance that the most prominent and distinguished exponents of relativity in England happened to be men whose work lay in the field of physics and astronomy rather than in mathematics, and who were not specially interested in questions of logic and rigour. It is, however, evidently of the highest importance that we should know exactly what assumptions must be made in order to deduce our equations, especially since the subject is still in a rather fluid condition.

What we want to do, then, is to set forth the axiomatics of general relativity in the same form as we have been accustomed to give to the axiomatics of any other kind of geometry—that is, to enunciate the primitive or undefined concepts, then the definitions, the axioms, and the existence-theorems, and lastly the deductions. In the course of the work we must prove that the axioms are compatible with each other, and that no one of them is superfluous.

The usual way of introducing relativity is to talk about measuring-rods and clocks. This is, I think,

a very natural and proper way of introducing the doctrine known as 'special relativity,' which grew out of FitzGerald's hypothesis of the contraction of moving bodies, and was first clearly stated by Poincaré in 1904, and further developed by Einstein in 1905. But general relativity, which came ten years later, is a very different theory. In general relativity there are no such things as rigid bodies-that is, bodies for which the mutual distance of every pair of particles remains unaltered when the body moves in the gravitational field. That being so, it seems desirable to avoid everything akin to a rigid body—such, for example, as measuring-rods or clocks-when we are laying down the axioms of the subject. The axioms should obviously deal only with the simplest constituents of the universe. Now if one of my clocks or watches goes wrong, I do not venture to try to mend it myself, but take it to a professional clockmaker, and even he is not always wholly successful, which seems to me to indicate that a clock is not one of the simplest constituents of the universe. Some of the expounders of relativity have recognised the existence of this difficulty, and have tried to turn it by giving up the ordinary material clock with its elaborate mechanism, and putting forward in its place what they call an atomic clock; by which they mean a single atom in a gas, emitting light of definite frequency. Unfortunately, the atom is apparently quite as complicated in its working as a material clock, perhaps more so, and is less understood; and the statement that the frequency is the same under all conditions, whatever is happening to the atom, is (whether true or not) a highly complex assumption which could scarcely be used in an axiomatic treatment of the subject until it has been dissected into a considerable number of elementary axioms, some of them perhaps of a disputable character.

It seems to me that we should abandon measuringrods and accurate clocks altogether, and begin with something more primitive. Let us then take any system of reference for events—a network of points to each of which three numbers are assignedwhich can serve as spatial co-ordinates, and a number indicating the succession of events at each point to serve as a temporal co-ordinate. Let us now refer to this co-ordinate system the paths which are traced by infinitesimal particles moving freely in the gravitational field. Then it is one of the fundamental assumptions of the theory that these paths are the geodesics belonging to a certain quadratic differential form The truth or falsity of this assumption may, in theory at any rate, be tested by observation, since if the paths are geodesics they must satisfy certain purely geometrical conditions, and whether they do or not is a question to be settled by experience

Granting for the present that the paths do satisfy these conditions, let us inquire if a knowledge of the paths or geodesics is sufficient to enable us to determine the quadratic form. The answer to this is in the negative, as may easily be seen if we consider for a moment the non-Euclidean geometry defined by a Cayley-Klein metric in

three-dimensional space. In the Cayley-Klein geometry the geodesics are the straight lines of the space; but a knowledge of this fact is not sufficient to determine the metric, since the Absolute may be any arbitrary quadric surface

In order to determine the quadratic form in general relativity we must, then, be furnished with some information besides the knowledge of the paths of material particles. It is sufficient, as Levi-Cività has remarked, that we should be given the null geodesics, i.e. the geodesics along which the quadratic form vanishes. In the Cayley-Klein geometry these are the tangents to the Absolute, in general relativity they are tracks of rays of light.

So from our knowledge of the paths of material particles and the tracks of rays of light we can construct the particular quadratic form, and then we are ready for the next great axiom, namely, Einstein's Principle of Covariance The point I wish specially to make is that in the above treatment there has been no mention either of length or of time: neither measuring-rod nor clock has been introduced in any way. We have left open the question whether the quadratic form does or does not represent anything which can be given directly by measuring-rods and clocks For my own part I incline to think that the notions of length of material bodies, and time of clocks, are really rather complex notions which do not normally occur in the early chapters of axiomatic physics. The results of the ether-drift experiments of D. C. Miller at Mount Wilson in 1925, if confirmed, would seem to indicate that the geometry which is based on rigid measuring-rods is actually different from the geometry which is based on geodesics and light-rays.

The actual laws of Nature are most naturally derived, it seems to me, from the Minimum Principle enunciated in 1915 by Hilbert. This principle is the grand culmination of the movement begun 2000 years ago by Hero of Alexandria with his discovery that reflected light meets the mirror at a point such that the total path between the source of light and the eye is the shortest possible. In the seventeenth century, Hero's theorem was generalised by Fermat into his "Principle of Least Time" that "Nature always acts by the shortest course," which suffices for the solution of all problems in geometrical optics. A hundred years later, this was further extended by Maupertuis, Euler, and Lagrange, into a general principle of 'Least Action' of dynamical systems, and in 1834, Hamilton formulated his famous Principle which was capable of reducing all the known laws of Nature—gravitational, dynamical, and electrical —to a representation as minimum-problems

Hilbert's minimum principle in general relativity is a direct application of Hamilton's principle, in which the contribution made by gravitation is the integral of the Riemann scalar curvature. Thus gravitation acts so as to make the total amount of the curvature of space-time a minimum: or, as we may say, gravitation simply represents a continual effort of the universe to straighten itself out. This is general relativity in a single sentence.

I have already explained that the curvature of space-time at any point at any instant depends on the physical events that are taking place there. in statical systems, where we can consider space of three dimensions separately from time, the mean curvature (ie. the sum of the three principal curvatures) of the space at any point is proportional to the energy-density at the point. Since, then, the curvature of space is wholly governed by physical phenomena, the suggestion presents itself that the metric of space-time may be determined wholly by the masses and energy present in the universe, so that space-time cannot exist at all except in so far as it is due to the existence of matter This doctrine, which is substantially due to Mach, was adopted in 1917 by Einstein, and has led to some interesting developments. The point of issue may be illustrated by the following concrete problem. If all matter were annihilated except one particle which is to be used as a testbody, would this particle have mertia or not? The view of Mach and Einstein is that it would not; and in support of this view it may be urged that, according to the deductions of general relativity, the inertia of a body is increased when it is in the neighbourhood of other large masses; it seems needless, therefore, to postulate other sources of inertia, and simplest to suppose that all inertia is due to the presence of other masses confront this hypothesis with the facts of observation, however, it seems clear that the masses we know to exist—the solar systems, stars, and nebulæ—are insufficient to confer on terrestrial bodies the inertia which they actually possess; and, therefore, if Mach's principle were adopted, it would be necessary to postulate the existence of enormous quantities of matter in the universe which have not been detected by astronomical observation, and are called into being simply in order to account for mertia in other bodies. is, after all, no better than regarding some part of inertia as intrinsic.

Under the influence of Mach's doctrine, Einstein made an important modification of the fieldequations of gravitation. He now objected to his original equations of 1915 on the ground that they possessed a solution even when the universe was supposed void of matter, and he added a term the 'cosmological term' as it is called—with the idea of making such a solution impossible. After a time it was found that the new term did not do what it had been intended to do, for the modified field-equations still possessed a solution the celebrated 'De Sitter world'—even when no matter was present; but the 'De Sitter world' was found to be so excellent an addition to the theory that it was adopted permanently, and with it of course the 'cosmological term' in the fieldequations; so that this term has been retained for exactly the opposite reason to that for which it was originally introduced.

The 'De Sitter world' is simply the universe as it would be if all minor irregularities were smoothed out: just as when we say that the earth is a spheroid, we mean that the earth would be a spheroid if all mountains were levelled and valleys filled up. In the case of the De Sitter universe, the levelling is a more formidable operation, since we have to smooth out the earth, the sun, and all the heavenly bodies, and reduce the world to a complete uniformity. But after all, only a very small fraction of the cosmos is occupied by material bodies; and it is interesting to inquire what spacetime as a whole is like when we simply ignore them.

The answer is, as we should expect, that it is a manifold of constant curvature. This means that it is isotropic (i.e the Riemann curvature is the same for all orientations at the same point), and is also homogeneous As a matter of fact, there is a well-known theorem that any manifold which is isotropic in this sense is necessarily also homogeneous, so that the two properties are connected manifold of constant curvature is a projective manifold, i e. ordinary projective geometry is valid in it when we regard geodesics as straight lines, and it is possible to move about in it any system of points, discrete or continuous, rigidly, ie so that the mutual distances are unaltered

We are thus brought to the question of the dimensions of the universe  $\dot{}$  What is the length of the complete straight line, the circuit of all space ? The answer must be furnished by astrophysical observations, interpreted by a proposition which belongs to the theory of 'De Sitter's world,' namely, that the lines of the spectrum of a very distant star should be systematically displaced, the amount of displacement is proportional to the ratio of the distance of the star from the observer to the constant radius of curvature R of the universe. In attempting to obtain the value of R from this formula we meet with many difficulties: the effect is entangled with the ordinary Doppler effect due to the radial velocity of the star; it could in any case only be of appreciable magnitude with the most distant objects, and there is the most serious difference of opinion among astronomers as to what the distance of these objects really is. Within the last twelve months the distance of the spiral nebula M 33 Trianguli has been estimated by Dr Hubble, of the Mount Wilson Observatory, at 857,000 light-years, and by Dr. Perrine, the Director of the Cordoba Observatory, at only 30,000 light-years; and there is a similar uncertainty of many thousands per cent. in regard to all other very remote objects.

In these circumstances we hesitate to assign a definite length for the radius of curvature of the universe; but it is millions of light-years, though probably not greater than about a hundred millions. The curvature of space at any particular place due to the general curvature of the universe is therefore quite small compared to the curvature which may be imposed on it locally by the presence of energy. By a strong magnetic field we can produce a curvature with a radius of only 100 light-years, and of course in the presence of matter the curvature is far stronger still. So the universe is like the earth, on which the local curvature of hills and valleys is far greater than the general curvature of the terrestrial globe.

# Influence of Internal Secretions on Sex Characters.

AT the Edinburgh meeting of the British Medical Association, Dr F A. E. Crew opened an interesting discussion in the Section of Physiology and Bio-chemistry on the "Influence of Internal Secretions on Sex Characters." The importance of the organs of the endocrine system in regulating and controlling sex characteristics has been recognised for the past thirty years or so, but it is only recently that we have come to have a clear understanding of the rôle of the component members of this glandular system and the balanced action which exists between them.

Crew classified the sex dimorphic characters as (1) primary genotypic, (2) secondary genotypic (including the primary gonadic), and (3) secondary gonadic. There is no difficulty in demonstrating the dependence of the secondary gonadic characters on the physiological activity of the gonad. It is now established that the gonad influences the growth of the long bones, the development of the muscular and nervous systems, and plays an important part in general metabolism. The gonad also exerts a powerful influence over the structure and functions which form the secondary sexdimorphic characters

The function of the genads in regulating growth and development may be studied by the usual experimental procedure, namely, (1) removal of the genad, (2) implantation of the genad, and (3) administration of preparations of the gland

The effect and results of removal of the gonad will vary according to the development of the body and the physiological condition at the time that the operation is carried out. These conditions may be summarised as (1) pre-pubertal, and (2) post-pubertal. The first result of castration before the age of puberty is the hinderance to further development of the reproductive system. Castration on one side produced no effect, the retention of a single testis being sufficient to maintain normal function. In the human, castration at the same stage is known to prevent the growth of hair on the face, the development of the thorax, pelvis, and to preserve the voice of childhood. Further, metabolism is disturbed, the deposition of fat is marked, accumulating under the breasts and in gluteal regions.

The effect of castration on the development of the long bones has been well studied, and the evidence is now clear that the absence of the active gonad leads to an abnormal growth of bony tissues. Poucet in 1897 found that the bones and skeleton of the castrated rabbit were larger than those of the control. Geddes has also shown that the process of ossification is prolonged, and that the long bones are unduly long. These findings do not necessarily imply that the processes of nutrition and growth are opposed to reproduction. After castration, there is not only absence of the internal secretion from the gland, but there is further a loss of balance in the endocrine system during a period of rapid development of the body

structure.

Castration after onset of puberty is followed by disappearance of the beard and redistribution of the body fat and hair. It is clear that castration never induces any condition resembling the female type, the condition is infantile and not female. Extirpation of both ovaries in the human after puberty is followed by cessation of menstruation. Atrophy of the genitalia is also well marked. The operation may also lead to emotional disturbances, headache, fainting, and intestinal disturbances

Probably the most interesting results which have been obtained are those on gonad implantation. There is no difficulty in demonstrating that an animal which has been castrated at an early age will develop normally if a testis is successfully implanted It is also possible to restore the female characters by implanting ovarian tissue after ovariotomy. The degree of restoration possible will depend on (1) the age of the animal at the time of castration or ovariotomy, (2) the condition of the tissues at the time of implantation, and (3) the interval between the two operations. It will be seen that restoration is not possible if pathological changes have taken place in the tissues after removal of the gonad. Further, secondary sex characters can be re-established, as has been shown by Nussbaum. Castration of the male frog inhibits the development of the sexual pad on the first digit of each fore-limb, but after introduction of pieces of testis into the dorsal lymph sac, the swelling on the thumb and hypertrophy of the muscles of the fore-limb took place as in the normal animal.

It is possible to feminise a male by castration and subsequent implantation of ovarian tissue; the mammary glands are stimulated into activity while the male sex organs diminish in size. The converse is also possible, namely, to masculinise a female by ovariotomy and subsequent implantation of testes. These experiments certainly suggest that the sex hormones are specific.

Much attention has recently been devoted to implantation of testicular grafts from anthropoids into the human host. The success of these operations will depend not only on the technique of the operation but also on the ability of the host to provide the nutrition necessary for the continued life of the implant. The effect of the graft on the body will depend on the condition of the tissues at the time of operation. It is possible to supply and supplement the gonadic hormone and to re-establish the balance between the components of the endocrine system. It is not possible, however, by increase of sex hormone to re-establish a physiological condition if pathological changes have taken place

In Crew's study of about one hundred and fifty hermaphrodite pigs, he has found only testicular tissue present, though usually intra-abdominally. The sex characters, however, fell into a graded series from a normal male up to an almost female type of animal. A certain minimum threshold of secretion exists which is essential before

differentiation of the sex characters can occur A condition of ovo-testes is frequently found amongst pigs either on one or both sides ovary is always cephalic and on the left side. showing that differentiation must take place from right to left and from cephalic to caudal poles. If the ovary was able to initiate the development. the animal would tend to develop female characters during its early days, the degree of maleness appearing later in life depending upon the extent to which the secretion of the slower differentiating testes was able to counteract the ovarian secretion This would explain the tendency to maleness exhibited in the human by girls as they grow Macmillan's recent discovery of a chemical test for sex should prove useful in the solution of these problems.

Evidence that the ovarian extract as at present used is responsible for the slow ante-pubertal growth of the female sex-organs is not conclusive The supposed hypertrophy is sudden, occurring within forty-eight hours, and it only produces the changes associated with cestrus. Injection into the new-born rat is without effect, while injection into the animal three weeks old produces æstral changes. Further, ovarian extract does not produce the psychical changes normally associated with the cestrus cycle Parkes, from his investigations, concluded that the ovarian extract at present in use probably contains the responsible factor for the production of œstral changes, and that another substance is responsible for the pubertal and psychical changes.

Evidence was put forward by Glynn in the discussion for the supposed relationship of the suprarenal cortex to secondary sex characters. This evidence is summarised under the four headings

- (1) Embryological—Cortex of the suprarenal gland and the ovary and testis are derived from the same source
- (2) Physiological—Enlargement of the suprarenal glands during pregnancy
- (3) Pathological—In hermaphroditism there is bilateral enlargement of the suprarenals in the female
- (4) Clinical—Hypernephroma or tumour of the suprarenal associated with pseudo-hermaphroditism

In females suffering from adrenal hypernephroma, there is often atrophy of the mammary glands, ovary, and uterus, with cessation of menstruation, alteration in metabolism, mainly fat metabolism, and a general tendency to increase the male primary and secondary sexual characters at the expense of the female

Tumour formation in the adrenals leads to a profound disturbance of normal metabolic conditions, and it is possible that while the endocrine glands may exert no direct influence upon the secondary sex characters, yet they may have a pronounced indirect effect by bringing about abnormal conditions of metabolism Crew has demonstrated that cockerels, fed on thyroid from the time of hatching, developed female colour and type of feathering. Further, gonadectomy and gonad implantation do not lead to any apparent change in the metabolism of the animal, and, after operation, the endocrine glands appeared to be normal appears probable, then, that the secondary sex characters are under control of the gonad secretion, but with abnormal conditions of metabolism, a new threshold for the differentiation of the tissues is established.

# The British Association at Leeds.

THE general opinion on all hands seems to be that the meetings of the British Association in Leeds have been a great success; certainly from the point of view of the citizens of Leeds, they will be remembered as a fitting celebration of the arrival of summer After the most dismal August in the recorded meteorology of the area, the meetings have heralded a change to sunny weather and blue skies, with that bracing keenness in the air that prevents lassitude. Whilst the excursions have thus been made doubly enjoyable, the weather has also been appropriate for the strenuous follower of sectional activities.

Comparatively few seats were empty when the president's address was delivered in the Majestic Picture Theatre. This meeting was noteworthy for the announcement by the president of the Council's support of a movement to purchase Charles Darwin's home and estate at Downe, so that it may be retained in perpetuity for the nation. The enthusiastic applause of the vast audience showed their cordial sympathy with the proposal. Sir Oliver Lodge, who, in the absence of the retiring president, H.R.H. The Prince of Wales, was in the chair and introduced Sir Arthur Keith, alluded in felicitous terms, as also later did the president him-

self, to the generous anonymous gift of £100,000 to the appeal fund of the University of Leeds—a sum to be devoted to the erection of the new library. The announcement of this gift in the press on the same day as the maugural meeting naturally added to the general enthusiasm with which the proceedings were initiated, and gave added force to the vice-chancellor's hope, expressed in his opening remarks of welcome at the inaugural meeting, that on a future occasion the University may be then able to accommodate all the activities of the Association within its walls It has since been announced that the University owes this gift to Sir Edward Brotherton, a well-known chemical manufacturer with works at Leeds and Liverpool, to whom the University was already indebted for a gift of £20,000 for bacteriological research. Sir Arthur Keith's reference to the possibility of acquiring Darwin's house at Downe has borne fruit, for an amount sufficient to purchase and maintain the house has been offered by Mr. G. Buckston Browne, whose name will be associated with this gift to the nation

Both the University and the civic authorities have thrown themselves whole-heartedly into the work of entertaining their guests; the dinners given to the president, vice-presidents, and other prominent members of the Association by the Lord Mayor and the vice-chancellor of the University being representative of a large amount of civic and private hospitality, in which neighbouring towns have also joined. Both York and Harrogate entertained large parties of scientific visitors right royally when the week-end permitted the members of the Association to scatter into various parts of the three Ridings.

One feature in the meeting that was perhaps particularly appreciated was the effort made to provide for the comfort of members on excursions. On all general excursions, besides the leader who explained the particular points of interest, another guide accompanied each party whose sole task was to consider the comfort of visitors, and in case of any emergency to see that arrangements were made to meet it without distracting the official leader

from his duties

Both the civic reception on Thursday evening and the University reception on the night of Tuesday, were very successful, if crowded, functions. Particular distinction was given to the civic reception by the presence of H.R. H. Princess Mary, Viscountess Lascelles, to whom a number of prominent citizens, vice-presidents, members of the Council, and officials of the Association were presented. Princess Mary afterwards made a tour round a number of the beautiful rooms of the Art Gallery which were thrown open to the throngs of visitors on this occasion.

Perhaps the most striking feature of the University reception to the visitors was the vast extent and elaborate equipment of the technological departments of the University which were thrown open for their inspection with a large amount of the full scale machinery in operation. Visitors were then able to see industrial processes, such as dyeing, manufacture and treatment of leather, spinning and weaving, etc., carried out upon a manufacturing scale and at the same time worked in conjunction

with intensive scientific investigation

On Friday night a most successful dance was held in the Dance Hall of the Majestic Picture Theatre. The Lord Mayor's party, which included the president of the Association and the vice-chancellor of the University, attended after a dinner given by the Lord Mayor in the Town Hall, whilst Sir Oliver Lodge was to be seen with the party coming fresh from listening to Prof. Millikan, who had been giving the first of the evening discourses to a large audience in the Albert Hall Sir Oliver danced nearly every item of the programme, and many citizens of Leeds present on this and other social occasions of the meeting will probably have gained quite a different conception of the human side of the scientific members of the community from that usually held, as a result of this and similar light incidents of a notable scientific assembly.

SCIENTIFIC APPARATUS AND DEMONSTRATIONS.

During the week of the meeting, demonstrations were given of Mr. J. L. Baird's television and 'noctovision' apparatus The latter (which em-

ploys infra-red radiation in the place of light) is regarded by the inventor as likely to be of commercial value at an earlier date than the former, since he hopes to apply it to navigation in fog The reproductions are at present comparable with those obtained with the earliest kinematographs, and are marred by flickering and coarseness of detail, but the inventor has in view some solutions of the outstanding problems which may well prove successful, like those adopted in the earlier art. Whether or not Mr Baird will be victorious in the competition with formidable foreign rivals which lies in front of him is a matter for speculation, but at least a tribute of admiration must be paid to the ingenuity, courage, and enterprise of a British inventor who has achieved considerable success in the teeth of great difficulties. An indulgent view may therefore be taken of some aspects of the exhibits which were more relevant to the popularisation of the invention than to its technical development

An exhibition of apparatus in the crypt beneath the Reception Room formed a valuable addition to the proceedings of the Association. The exhibition was generally similar to, though on a smaller scale than, that held annually in London by the Physical and Optical Societies, and it is to be hoped that such an exhibition will become an annual feature of the meetings, since it enables scientific workers from all parts of the country to see some of the latest improvements in scientific apparatus is of course impossible to mention many of the most interesting exhibits, but a word must be said of that contributed by the Lancashire and Cheshire Coal Research Association, which included some most interesting fossil remains illustrating the natural history of coal, in addition to preparations and samples of coals and their ingredients wool research reflector for assuring even illumination in colour comparisons was attributable to the Woollen and Worsted Industries Research Association, but research associations generally did not take this opportunity of illustrating their work for the benefit of fellow investigators and others likely to be interested in it. Amongst the more recent applications of science to practical purposes, the use of an analytical quartz lamp for such purposes as the testing of bank notes and the examination of palmpsests was illustrated. The emitted radiation is restricted by a filter to a band in the neighbourhood of 3660 Å.U., and the fluorescence produced gives a sensitive indication of slight variations in the irradiated surface. Another interesting exhibit was a refrigerator without mechanical moving parts, a quantity of captive ammonia being forced through a repeating eyele of condensations and evaporations merely by the application of heat to one vessel and of cooling water to another connected with it. Refrigeration is effected by evaporation produced by mixing the liquid ammonia with hydrogen.

Visitors to Leeds this year had an opportunity of making themselves better acquainted with a medium which is already finding its place in the service of education, namely, broadcasting. Many

No. 3019, Vol. 120]

people are coming to feel that what the school of to-day most urgently needs is enrichment, and this topic was the theme of many discussions in Section L (Education). In fifty years we have evolved a machine capable of high efficiency in turning out pupils reasonably well equipped for beginning to acquire knowledge, but still there are those masses who must leave school at 14 years of age with only the dimmest perception of the treasures of science and art that are their rightful inheritance. Let any one who doubts this study the text books in use in the public elementary school or hear their musical instruments or ask to see their scientific apparatus, or their playgrounds But those who see the deficiencies most acutely are in despair at the cost of providing a proper equipment under present economic conditions, and it is for this reason that they are turning their attention to a new means of enlarging the scope of a school however remote and enriching its resources without excessive cost.

At the Reception Room, some hundreds of people were able to hear the special programmes arranged by the British Broadcasting Corporation to enable schoolmasters and others to judge how clearly and naturally broadcast matter can to-day be presented in the class-room At the University a large room was divided into two parts, one of which represented a model studio, while the other did service as a class-room. A large number of members visited these rooms during the week, especially during the evening of the reception, and there were many who appreciated, perhaps for the first time, the extent to which it is possible for a speaker to project his personality into a room full of people, even when the appeal that he makes is to the auditory and not to the visual sense. Some thousands of schools are now listening regularly to these transmissions, using them to supplement the ordinary curriculum.

The new programme and syllabus of transmissions to schools and the provisional programme for adult transmissions are now ready and can be obtained from the British Broadcasting Corporation on application.

In connexion with a paper on the slaughtering of animals for food, a demonstration was given by the Royal Society for the Prevention of Cruelty to Animals in the municipal slaughter-house. After 12 pigs, bullocks, calves, and sheep had been dispatched with a captive bolt pistol (humane killer) a local butcher who was opposed to this instrument asked permission to demonstrate the use of the poll-axe on a bullock. The first blow of the axe proved ineffective, and a second had to be given before the bullock was felled.

#### TEXTILE RESEARCH.

As was fitting for a meeting held in Leeds, special provision was made for the discussion by the sections concerned of textile problems. The British Research Association for the Woollen and Worsted Industries issued a 48-page pamphlet by Dr S G. Barker and A. Frobisher dealing with its origin, constitution, and work in connexion with

the special meetings arranged for the discussion of The Association is of firms engaged directly or accessorily in the woollen and worsted industries, and its headquarters are in Leeds. Among the most debatable of textile problems is that of the 'quality' of the raw material, the fibres Judgment based upon the observations of sight and touch and crystallised by experience, grades cotton, classifies wools and tops, and selects silks with an accuracy that has sufficed for many generations of manufacturers and will no doubt continue to do so, at least to some extent, tor many years to come But science holds no realm that admits of investigation too sacred or too unfruitful for such investigation, and elasticity tests, grease estimations, diameter measurements, staple lengths, all now contribute to a more accurate, more trustworthy estimation of 'quality,' though the writers of this pamphlet wisely state that "the precise factors affecting quality as regards spinning are as yet unknown," and again, one of the outstanding problems in wool research is the investigation of the precise definition of the term 'quality'" The amount of work being done upon a determination of the measurements and properties of wool fibres may be gauged from a list of the headings under which the chemical aspects of the problem are surveyed—the action of acids, alkalis, and soaps, the estimation of alkalı and of sulphuric acid, the sulphur content; bleaching and chlorination; and the action of ammonia; and the chemical decomposition of wool at 100° C.

The physical properties of wool have also been the subject of carefully thought out investigation, and the work of Dr. Shorter, at one time on the staff of this Association, is sufficiently well known to need but mention. Since his departure, the work of evaluating the properties of wool—regarded as an amphoteric colloid—has proceeded apace, and elasticity, regain, thermal conductivity, and electrification are topics of investigation noted in the work of the Association's physical laboratory. The action of bacteria and mildews upon wool has also been the subject of, at any rate, preliminary work, though in these aspects as well as the chemical and physical aspects the work is described as "only a beginning of the attack on the great problems." "The scientific side must be closely related to the technical or trade side, and valuable as the scientific data are, yet the object of their discovery must be their application to the industry" The Association's claim that this point is ever to the fore in its work is well substantiated, and the relationship of the previously determined chemical and physical properties to such technical problems as the migration of alkali when scoured cloth is drying off from the damp state and the faults engendered thereby in subsequent processes, notably dyeing, wool scouring, the elimination of tar-marking and branding, and the all-important subject of the fading of dyestuffs, are all instances of this type of valuable work.

The comprehensive lecture delivered by Dr. S. G. Barker on the subject of the fading of

dyestuffs made it clear that here was a piece of work of which much has been done, but of which much—the greatest part perhaps—vet remains to Work yet closer to the trade processes has also been done, and apparatus likely to be of general use has been devised, the Research Association stroboscope may be mentioned in this The list of publications of the Association which, with a plan of its buildings, concludes the pamphlet, is an excellent indication of the comprehensive character of its work, and it is perhaps regrettable that the liaison between those engaged in pure science and those in technical research is not stronger and more generally No doubt wider publication of the established work of research associations might help materially in this respect.

# HONORARY DEGREES.

In a congregation of the University of Leeds in the Great Hall on Tuesday, Sept. 6, at 12 noon, the following honorary degrees were conferred:-LL.D.: Sir Arthur Keith, Conservator of the Museum and Hunterian professor of the Royal College of Surgeons of England, Her Grace the Duchess of Atholl, Parliamentary Secretary, Board of Education; The Hon. Sir Charles Parsons. D.Sc.: Prof. J. S. Haldane, honorary professor and director of the Mining Research Laboratory, Birmingham University; Dr N. V. Sidgwick, reader in chemistry in the University of Oxford, Prof F. O. Bower, emeritus professor of botany in the University of Glasgow, Dr. R. A. Millikan, chairman of the Executive Council of the California Institute of Technology and Director of the Norman Bridge Laboratory of the Institute. Ph.D.: James Graham, Director of Education, Lecds

#### REPORT OF COUNCIL.

The report of the Council presented to the General Committee on Aug. 31, expresses profound gratitude to Sir Alfred Yarrow for his munificent gift of £10,000 to the funds of the Association for general purposes, and accepts the wise condition that the gift should be expended as to both capital and interest within twenty years.

The Council has had under discussion with the Board of Trade the question of the duty required

by H M Customs on the introduction of kinematograph films into Great Britain for scientific purposes and not intended for commercial uses. The matter was referred to the Lords Commissioners of H M. Treasury, from whom a reply was received that "having regard to the impracticability of framing a statutory exemption which would be free from grave difficulties of definition and administration," they were unable "to submit to Parliament proposals of the nature desired by the Association."

Reference is made in the Council's report to the two conferences called to consider the possibility of establishing a Science News Service—The essential condition for success of such a scheme is that scientific societies and institutions themselves

should desire its organisation.

In view of the lack of unanimity and of enthusiasm evenced at the two conferences, the committee appointed to indicate the ways in which this support might be given, considers that no useful purpose would be served by communicating with the scientific societies. The opinion is expressed, however, that should sufficient funds be forthcoming for the establishment of a Science News Service, the Council of the Association—possibly in co-operation with the British Science Guild—might appropriately undertake the organisation of the service.

The Council has had under consideration the question of inviting "the co-operation of the British Science Guild in considering whether, having regard to the close community of scientific interests between the Association and the Guild, their objects would, as the Council believe, be more fully attained by means of a working union between the two societies; and if so, by what means such umon would best be given effect." A joint committee of the two bodies has prepared a report in which the general methods by which such a fusion might be effected are stated. This report came before the General Committee of the Association on Sept. 6, when it was decided that the Council be authorised to continue the negotiations and report to the meeting of the General Committee at Glasgow.

Next year's meeting of the Association will be held at Glasgow under the presidency of Sir William Bragg. The meeting in 1929 will be held in South Africa, and invitations have been received to meet at Bristol in 1930 and Leicester in 1932.

# Obituary.

PROF. H. R. PROCTER, F.R.S.

HENRY RICHARDSON PROCTER, born at North Shields in 1848, was the son of a tanner, a member of the Society of Friends. He was educated at Bootham School and received his scientific training at the Royal College of Chemistry and the School of Mines. He entered the tanning industry and remained on Tyneside until 1891, when he was invited to the Yorkshire College, Leeds, to take charge of a new department to be opened there in the special interest of the leather industry. In this Procter achieved distinguished success, and his work

afforded as fine an example as could well be cited of the part which applied science may properly take within the circle of university studies. Students came to Procter from all parts of the world. He was a thorough man of science, an eager and fruitful investigator, and an excellent teacher. He gave to the industry the means of scientific control and development in many directions, and placed his discoveries freely at its disposal. His text-books have long been the standard works in the science of leather manufacture.

Though Procter's scientific studies were centred

upon the problems of the leather industry, he revelled in pursuing their general theoretical bearing, and wherever they carried him he read himself in with great thoroughness It was typical of his mental proclivities that he should have been the translator of the first text-book of practical physics -Kohlrausch's—that found general use in physical laboratories in Great Britain. His later researches on gelatine were of fundamental importance and exhibited his power of dealing with the most abstruse problems of colloid chemistry

September 10, 1927]

Beyond this, Procter was a man of wide culture, keenly interested in languages, literature, and philosophy. He was an excellent countryman and had much of the artistic sense which has appeared

so strongly in his sons

The value set upon Procter's work was so great that when the time arrived for his retirement, a movement took place for the establishment of a research laboratory which should serve as a memorial and as a place where he could continue his investigations This project secured international support, and in 1914 Procter became the first honorary director of the international research laboratory at Leeds bearing his name The honour done to Procter was fully earned by the scientific and industrial value of his labours, but it was intensified by the respect and affection in which he was held for his personal qualities His fine character, his devotion, unselfishness, and modesty, together with his great companionableness, endeared him alike to his pupils, his colleagues, and the members of the industry to which he rendered such memorable service.

Procter was elected fellow of the Royal Society in 1923 and received the honorary degree of D.Sc. from the University of Leeds honorary president of the International Association of Leather Trade Chemists, of which he was a founder, and he received the freedom and livery of the Leathersellers' Company. He died on Aug 17 at Newlyn, Cornwall, where he lived in happy retirement after leaving Leeds.

### Prof. E. B. Titchener

THE announcement of the death of the English psychologist, Prof. Titchener, in his sixty-first year, which occurred after a short illness at Ithaca, N.Y., on Aug. 3, will be received in Great Britain with mingled feelings of regret and surprise. Regret will be felt for the loss of one who spent his abundant energies so generously in nursing to adolescence a new-born science. Surprise will be felt at the tidings that Titchener remained an Englishman, despite his thirty-five years' residence at Cornell University, and that with his full record of work he had only attained the age of sixty years at the time of his death.

Edward Bradford Titchener was born at Chichester on Jan. 11, 1867. From Malvern College he entered the University of Oxford in his nineteenth year, where he became a classical scholar at Brasenose, obtaining first class both in Moderations in 1887 and in Literae Humaniores in 1889. He took his BA in 1890, his MA in 1895, and in 1906 he was awarded the degree of D Sc at that University. From classics and philosophy he passed to the study of physiology at Oxford, and worked there as a research student during the year 1889–90. Attracted to experimental psychology, he proceeded to Leipzig, where he studied under Wundt and obtained the Ph.D. degree in 1892. Returning later in this year to Oxford, he began to inquire into the possibility of obtaining a permanent teaching post in experimental psychology, while he was giving university extension lectures in biology He was advised by Burdon Sanderson, however, that there were no immediate prospects in England, and consequently he accepted the immediate offer of an assistant professorship in psychology at Cornell.

Here from 1892 onwards Titchener spent the remainder of his life In 1895 he was made Sage professor of psychology, and in 1910 his professorship became attached to the Graduate School of the University. His specific aims at Cornell were to emancipate psychology from the leading-strings of philosophy, to establish undergraduate, as well as post-graduate, instruction, to compile a graded series of text-books in psychology, and to organise laboratory research in the subject His achievement of these aims was indeed remarkable twelve years he had established a completely independent department of psychology, in which finally he had a staff of two professors, two instructors and He had an annual entry of nearly three assistants one thousand undergraduates. In 1896 he published "An Outline of Psychology" (replaced in 1910 by his "Text-book of Psychology"). In 1898 his "Primer of Psychology" appeared (which in 1915 was replaced by "A Beginner's Psychology"). In 1908 his book on "Feeling and Attention" was published, followed in 1909 by "The Experimental Psychology of the Thought Processes "

Titchener's magnum opus, however, a thirteen years' task, the financial cost of which, he used to say, nearly ruined him, was his "Laboratory Manual of Experimental Psychology," issued in four volumes during the years 1901-5. While preparing this monumental work, he devised and standardised many useful pieces of apparatus for laboratory teaching. It was translated later into most European languages, and into Chinese and Japanese. It was the source of many later more elementary text-books, and it led to requests for his help in planning psychological laboratories in

practically every part of the world.

In 1917 a commemorative volume of essays, marking the close of twenty-five years' teaching work at Cornell, was presented to Titchener by his friends and students. By the end of 1923 the number of his published articles had amounted to 190, while the papers issuing from his students (for which he was personally responsible) numbered 158. From 1894 until 1920 he acted as American editor of the British philosophical periodical, Mind, and during the years 1894–1925 he was associate editor, and finally editor, of the American Journal of Psychology.

Titchener's unbounded energy and his abilities

were suitably rewarded in the United States. became Lowell lecturer at Cambridge, he was invited to give special courses of lectures at Columbia, Illinois, and elsewhere He received the honorary degrees of D Sc at Harvard, Litt D at Clark, and LL D. at Wisconsin. But throughout he remained a loyal British citizen and faithful to Cornell, refusing posts and honours that would have involved a change of nationality or a change of resi-He was offered, but declined, not only the chair of psychology at Harvard on Munsterberg's death, but also the presidency of Clark University, which became vacant on the retirement of Stanley Hall As an Englishman, he could never be a candidate for admission to the U.S. National Academy of Sciences.

Though, however, so loyal as to nationality, Titchener's psychological sympathies ever centred around Wundt, in whose laboratory at Leipzig he had received his first introduction to experimental psychology. His attitude towards his students and his organisation of laboratory work were also typically German. His admiration for Wundt led him to translate into English the third edition of the "Physiologische Psychologie" Takıng his manuscript to Germany, he found that Wundt was already issuing the fourth edition of this large work. Titchener set himself forthwith to make a translation of the fourth edition, only again to find on its completion that he had been overtaken by the fifth edition. Still undaunted, he began to translate the fifth edition, and he finally published a part of this translation. He also translated Kulpe's "Outlines of Psychology." At the time of his death he was engaged on a work of his own, which he hoped to issue in the form of a "Systematic Psychology" in three or four volumes, the first of which he had practically completed before he passed away.

Titchener's married and domestic life was an exceptionally happy one. His home on Cornell

Heights was delightful to visit He suffered from all the virtues and failings of an unusually emotional He was unduly sensitive to neglect temperament or injustice, and he did not easily brook any disagreement from his psychological views, especially on the part of his students and staff - On the other hand, no one could surpass him in kindness and generosity to his friends—He spent practically all his time in the laboratory or in his home, he was so rarely seen in the streets that it became a standing joke as to how he passed from one to the other. During his last years he began to form a collection of Oriental coins, which with his usual thoroughness he made one of the finest in America, learning Arabic in order to be able to read their inscriptions He was interested in music, and during the years 1896-98 he acted as professor in charge of music at Cornell University.

# WE regret to announce the following deaths

Sir John Benton, K.C.I.E., formerly chief engineer and secretary to the Government, Panjab Irrigation Branch, who was responsible for many of the great canal and irrigation schemes of the Panjab and Upper Burma, on Aug. 29, aged seventy-seven years.

Prof. C. Pulfrich, of the Zeiss optical works, Jena, the author of numerous publications dealing with his investigations with the spectrometer and refractometer,

aged sixty-nine years.

Dr. Henry P. Talbot, for many years professor of analytical chemistry in the Massachusetts Institute of Technology, and a vice-president of the American Association in 1907, on June 18, aged sixty-three

Prof. Stuart Weller, professor of palæontological geology in the University of Chicago, who specialised on the faunas of the Mississippi valley, on Aug. 5, aged

fifty six years.

Dr. William P. Wilson, formerly professor of botany at the University of Pennsylvania, and since 1894 director of the Philadelphia Commercial Museums, on May 12, aged eighty-two years.

### News and Views.

THE Government scheme for linking up the Dominions with Great Britain by radio telegraphy has now been completed by the opening of the short wave beam stations to India. The fact that the Indian beam stations can work at high speed continuously for many hours during the monsoon period shows that the beam receiving aerials are little affected by atmospherics. The English transmitting station is at Grimsby and the receiving station is at Skegness, which are both in direct communication with the Central Telegraph Office of the G.P.O in London. The corresponding transmitting and receiving stations in India are at Kirkee, near Poona, and Dhond, 48 miles east of Poona, which are both linked directly with Bombay. Transmission from Grimsby to India takes place on wave-lengths of 16 2 and 34 5 metres (about 18,500 and 8700 kilocycles per second respectively). At Grimsby a five-mast aerial system, quite distinct from the three-mast aerial system of the Australian service, has been built. The masts are

277 feet in height with a distance of 650 feet between them. They are erected in a straight line which cuts at right angles the great circle passing through Grimsby and Dhond. The reflector behind the active aerials focusses the waves in a south-easterly direction on to the receiving aerials in India. A similar system has been built at Kirkee to concentrate the waves in a north-westerly direction towards England. Within a few weeks' time the Marconi Company will maugurate a commercial beam radio service between Great Britain and South America and also one with the United States. Experiments have proved that it is possible to carry on radio telephony simultaneously with high-speed radio telegraphy There is every prospect, therefore, that before the end of next year, it will be possible for telephone subscribers in England to call up subscribers in any of the Dominions overseas.

The celebration, on Aug. 30, of the golden wedding of Prof. H. E. Armstrong and Mrs. Armstrong was

made the occasion for the presentation to them of the portrait of Prof. Armstrong by Mr. T. C Dugdale, exhibited in this year's Royal Academy. The presentation was made at a reception held at the house of Dr. Stephen Miall and Mrs. Miall, son-in-law and daughter of Prof. and Mrs. Armstrong. With the portrait was presented an illuminated album signed by the subscribers, among whom are a number of

leading workers ın diverse departments chemical science. We are glad to be able to reproduce a photograph of the painting (Fig. 1) The address which accompanied it reads as follows:

"PROFESSOR AND M R SHENRY EDWARD ARMSTRONG. Your Staff and Students of Chemistry of former years greet you with affectionate 1egard on this happy occasion of your Golden Wedding. As they are scattered all over the world, only a comparatively small body of them can subscribe to this personal Letter of Greeting, but in so doing, and in endeavouring to honour their Chief and his Lady, they

know they are voicing the good wishes of all They know, Professor Armstrong, their Colleagues. that by your teaching, your breadth of vision, and your scientific use of the imagination, coupled with a sympathetic guidance and a real human understanding, you have inspired those who have been privileged to work with you to their lasting benefit The consciousness of this grows with them; so, with perhaps a pardonable pride, they have purchased your portrait in this year's Royal Academy to mark the present occasion. They ask your acceptance of this portrait for the period of your lives, earnestly trusting that such useful lives may long be spared. Eventually, however, they propose presenting it to

one of the London learned Societies in commemoration of a striking personality and as a lasting record of their appreciation and affection "

The installation of receiving sets for broadcasting has familiarised many with the idea of what electricians mean by an 'earth.' The subject is sometimes eagerly discussed by amateurs, and the difficulties

experienced by

FIG 1 -Prof Henry E Armstrong, F.R S From a painting by T. C. Dugdale

those who installed lightning conductors many years ago are again being considered. For earthing the conduits used for protecting electric light wires, the Institution of Electrical Engmeers is carrymg out experiments so as to enable a good method of earthing to be speci-In the fied. Electrical Review for Aug. 19, some suggestions are made for improving the methods of earthing electric lighting systems used at both generating and substations. In this case a very large earth curient may flow if a fault develop in the system and it is necessary to make the joints and connectors large. permanent, and

trustworthy. The resistance of the path in the earth varies with the composition and the moisture content. In dry weather it is often fifty times as great as in wet weather. Sometimes, when permanently damp soil cannot be reached, a pipe is run into the ground near the earth connexion and water poured into it in dry weather. It is known that the resistance of the 'earth' increases very rapidly at the freezing point. In Great Britain, however, it is unlikely that earth plates are likely to be buried in soil which is ever frozen. Iron pipes an inch in diameter can be used successfully to form an earthing system. Unless the ground is rocky, they can be driven into it until damp'soil is reached. It is very seldom that a depth of 20 feet is necessary. A number of these pipes about four feet apart and connected in parallel form a suitable earth for a supply network. Tests should be made to see whether the earth is capable of carrying the maximum possible 'fault' current. It is quite possible for an arc to form between loosely packed pieces of carbon and so melt the soldered connexions. Hence periodical tests should always be made.

THE rapid development of electric signs during the last few years has made many think that a more rigorous censorship of sententious texts and childish pictures is desirable. It shows the belief that advertisers have in the efficacy of continued repetition. In the July issue of Progress, published by the Allgemeine Elektricitats-Gesellschaft of Berlin, there are interesting articles on electric signs and the flood lighting of buildings. A successful method of attracting attention, which is rapidly becoming popular, is to have an instantaneous time indicator, the large figures giving the time being controlled by a master clock. Stress is also laid on the importance of arranging the signs so that they are visible in daylight. Neon tubes seem specially suitable for the purpose. They are rather expensive to buy, but the saving of electricity during the first year by their use more than covers their cost. There can be no doubt, however, that the appearance of a street at night can be improved by 'flooding' beautiful buildings in it with light. Examples of flood lighting have been familiar to dwellers in London for many years, and we think that they provide a pleasing and unobjectionable method of advertising. Some interesting photographs shown in Progess of the effects that can be produced at no great expense by flood lighting. In particular we would mention the Cathedral and banks of the Rhine at Bâle. The flood lighting also of St. Mary's Church at Lubeck shows up excellently against the dark background. In Germany, many municipal authorities and tramway companies grant permission readily to shopkeepers and others to mount cheap projectors for flood light purposes on the tramway and lighting poles.

EVER since the last attempt to reach the summit of Mount Everest in 1924, Italian climbers have been planning an expedition with the same end in view. The Times reports that the plans of the Italian expedition are now complete. The expense is to be borne by the city of Milan and the expedition is to be organised by the Mılan Alpıne Club. The Italians propose to approach the mountain from the Nepal side, which will necessitate the approval of the rulers of Nepal. This has hitherto been refused for any attempt on Mount Everest. If the veto is not removed, the Italian expedition proposes to make its object Mount Godwin-Austen (K2) in Kashmir, which is about 28,250 feet in height, and is said to offer difficulties fully as great as those of Mount Everest.

DR. DOROTHY JORDAN LLOYD has been appointed director of research to the British Leather Manu-

facturers' Research Association in succession to Dr. R. H. Pickard. Dr. Lloyd has been a member of the staff of the Association since its inception and has published papers on the chemistry of gelatine Dr. Pickard's services will be retained for a time as consultant-director.

IT will be recalled that a Lister Centenary Exhibition was arranged at the Wellcome Historical Medical Museum, 54A Wigmore Street, in connexion with the centenary celebrations in London in April last. The Exhibition has already been visited by a large number of visitors from all parts of the world, and will remain open until Oct. 1.

The July issue of The Fight against Disease, the journal of the Research Defence Society, contains a short obituary notice with excellent portrait of the late Prof. Starling, who gave unceasing support to the Society, and a report of the first Stephen Paget Memorial Lecture by Prof. Julian Huxley, entitled "Research and the Community." Quoting examples of the control of plant and animal pests by biological methods, of the breeding of strains of wheat immune to rust, and of the control of many human diseases, Prof. Huxley emphasised the importance of research to the whole community.

The new Radiological Department of the Royal Infirmary, Edinburgh, was opened last October and is under the charge of Dr. J. M. W. Morison. A description of this department has been issued in the form of a brochure by Messrs. Watson and Sons (Electro-Medical) and will repay study by those interested in the lay-out and equipment of a radiological department, one of the most vital in the needs of a big hospital. There are others also to whom it may be of interest as showing the extent to which electro-technical invention is used by radiologists at the present time. The plans of the building are reproduced by courtesy of the architect, Mr. T. W. Turnbull.

The Report of the Director-General (Mr. Robert Dick) of Public Health, New South Wales, for the year 1925, which has recently been issued, contains a record of the public health administration, communicable diseases and industrial hygiene of the State, and a report of investigations conducted in the microbiological laboratory. Dr. Badham describes an explosion in a sugar-refining factory which caused three deaths. The explosion was caused by the ignition of sugar dust, apparently by the breaking of the bulb of a portable electric lamp, while the men were clearing an accumulation of sugar dust from a dust-collecting system. A few explosions in flour mills caused in the same manner have been recorded.

THE Section of Geodesy of the International Union of Geodesy and Geophysics has recently issued Tome 2 of its *Travaux*, containing general reports prepared in connexion with the Rome assembly in 1922, though not then presented. They refer to the period 1912–1922, between the last meeting of the old International Geodetic Association at Hamburg, and

the Rome meeting of the new organisation, and may be regarded as continuing the triennial reports presented to its predecessor. The volume is of considerable size, the principal contents consisting of a comprehensive report on determinations of latitude, azimuth, and longitude, prepared by H. L P Jolly, research officer to the Ordnance Survey; a report by E. de Martonne on the 1913-1914 campaign of geodetic astronomy executed by the geographical survey of French West Africa; and a report by E. Soler, professor of geodesy at Padua, on relative measures of the intensity of gravity in all parts of the world. There are also shorter reports by G. F. Dodwell on radio determinations of longitude in Australia, and by J. de Graaf Hunter on deviations of the vertical.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A man or woman on the staff of the Association of Special Libraries and Information Bureaux to compile supplementary data for the "Aslib Directory of Sources of Specialised Information"—The Secretary, Aslib. 38

Bloomsbury Square, W.C.I (Sept. 15). A lecturer in mining at the Denbighshire Technical Institute, Wrexham-The Secretary and Director of Education, Education Offices, Ruthin (Sept. 17). A temporary assistant lecturer in education at the University College of Swansea—The Registrar, University College of Swansea, Singleton Park, Swansea (Sept. 20). A deputy director of agriculture under the Government of the Punjab - The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, SWI (Sept. 24). An assistant examiner of Questioned Documents under the Government of India, with knowledge of chemistry, especially analytical chemistry, and of physics and photography-The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (Sept. 26). A mycologist for research at the Imperial College of Science and Technology on wood-destroying fungi-The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Sept. 26). Civilian education officers of the Royal Air Force, with practical qualifications for teaching engineering subjects—The Secretary, Air Ministry, Adastral House, Kingsway, W.C 2.

#### Our Astronomical Column.

An Extremely Massive Multiple Star.—The star 27 Canis Majoris has been examined spectroscopically by Dr. O. Struve, and found to be a most interesting quadruple system. His results, which are published in the Astrophysical Journal, vol 65, p. 273, show that two independent spectra are visible. These are of types B5ne and B8, and correspond to the two principal components of the system, which have a period of revolution of 3.2 years. Each of these components has, in addition, a much shorter period, indicating the presence of invisible companions. The masses of the stars in this system are found to be unusually large, the minimum value of the total mass being 950 times that of the sun. The masses of the two principal pairs (A+B) and (A+B) and (A+B) are approximately equal, but the ratios (A+B) and (A+B) are not known. The mass of each star, however, must be in the average at least 238 times the solar mass. Attempts to attribute the line shifts to causes other than radial velocity are very unsatisfactory, and there seems at present to be no alternative to the acceptance of these enormous masses.

Tables for Ephemerides in Parabolic Orbits.—Some years ago a modification of the familiar equations, due to Gauss, that give the rectangular heliocentric co-ordinates x, y, z, was published; in this the co-ordinates are given in terms of  $\tan v/2$  and  $\tan^2 v/2$  multiplied by factors deducible from the elements of the orbit. Mr. Bengt Stromgren has calculated useful tables, which are published in Meddelelser fra Kobenhavns Observatorium, No. 58, and in B.A.A. Memoirs, vol. 27, Part 2. These give the natural values of  $\tan v/2$  and its square, the argument being M, which is the interval from perihelion in days multiplied by  $q^{-1}$ . The values are given to five decimal places, so they suffice for fairly accurate ephemenides, but not for rigorous ones. They extend to  $120^{\circ}$  from perihelion; comets are seldom observed farther than this unless q is very small. The tables are designed for use with a calculating machine, and will considerably reduce the labour of forming an ephemeris

STARS WITH BRIGHT IRON LINES.—Among the emission lines which are found in stellar spectra, the lines of iron occur more frequently than those of any other element except hydrogen. Stars in which these lines are found may be divided into four groups, namely, long period variables, peculiar stars of late types, stars of type Be, and novæ. In the Astrophysical Journal, vol. 65, p. 286, Dr. Merrill gives list of stars showing bright iron lines in the general and of stars showing bright iron lines in the second and third of these groups, as well as discussing all the available information concerning them. One point of great interest which emerges from this discussion is the fact that only the lines of ionised iron appear as emission lines in the majority of stars. This is the case even in the low temperature stars which possess very strong are lines in their absorption spectra. The only stars in which emission lines of the neutral atom occur are the long period variables, and even in these cases enhanced lines are also present. It also appears that bright iron lines are found mainly in stars near the two extremes (B and M) of the temperature sequence, being absent in types A and F.

REPORT OF THE ROYAL OBSERVATORY, CAPE OF GOOD HOPE.—The annual report for 1926 of the Royal Observatory, Cape of Good Hope, has just been issued. The meridian observations include all stars south of Decl. – 30° down to mag 7.5. Heliometer observations of planets are also being made. Dr. J. Lunt, who has been using the Victoria telescope for stellar spectroscopy for thirty years, has now retired; a programme of stellar parallaxes with the instrument has been commenced. The Cape section of the Astrographic Catalogue is now almost complete, the last volume being in type. It is noted that the number of meridian observations and of solar photographs are in excess of any previous year. A new clock, Shortt No. 10, has been obtained from the Synchronome Co., and is working satisfactorily. A radio time signal is sent out daily for the use of shipping in South African waters; another one is distributed three times daily by the local broadcasting association.

# Research Items.

THE ORIGIN OF THE MASAI —In the Journal of the East Africa and Uganda Natural History Society, No. 28, Mr. C. L. Bolton criticises the theories on the origin of the Masai and other non-Bantu races of Kenya and Uganda which were advanced by Mr. C. C. Luck in the *Journal* for August 1926. Mr. Luck suggested that the Masai were the descendants of the half tribe of Manasseh from the west of Jordan and the Nandi of Moab, and that there were many proofs of the influence of the ancient civilisation of Egypt-Mesopotamia in Central Africa. Mr Bolton maintains, however, that Sir Charles Eliot's arguments against the Semitic origin of the Nilotic languages have never been met, while physically the Masai and Nandi exhibit none of the signs of a Semitic cross. The cultural evidence collected by Mr. Luck points to Egyptian influence. In addition, spitting for luck and on meeting a person is characteristic of the Mediterranean peoples, and dislike of swine, bewitching by means of anything from the body, aversion from the use of proper names for fear of witchcraft, the sun worship of the Nandi and the possible derivation of L'Oibon from the word for snake and wizard also point to Egypt. The Mosaic traditions noted by Merker may have originated in Egypt before the Jews left the country and hence reached central Africa, or they may have been introduced by Mohammedans or even by Jews trading up the Nile. As an alternative theory of origin, it is suggested that the Somali and Galla are the lineal descendants of the Macrobians of Herodotus, and as independent but unambitious people may have inhabited their present country possibly for thousands of years. The Masai and Nandi may be of Bantu stock crossed with a race from Egypt, possible the Automoli of Herodotus, perhaps themselves a mixed race who drove the Bantu peoples out and took their women. These Bantu still exist as the Wakamba, Kikuyu, and Kitosh. The Bahima appear to be Hamitic negroes with a dash of Aryan blood which may be due to a Persian infiltration of adventurers at the time of the conquest of Egypt by Cambyses.

BRITISH GALL MIDGES OF ECONOMIC IMPORTANCE —The Journal of the South-Eastern Agricultural College, Wye, No. 24, July 1927, contains an important paper (pp. 65-146) by Mr. H. F. Barnes on British Cecidomyidæ or gall midges. In this memoir Mr. Barnes has gathered together all the essential information concerning these insects, while new and unpublished observations are also added. Under each species is given the original description (or, sometimes the first available one), its distribution, biology, control measures and parasites, wherever sufficient data are available. At the end of the paper there is a hibliography containing about 380 references and a useful index both of gall midges and of the plants which they affect. A comprehensive summary of this character, particularly in so obscure a family as the C'ecidomyidæ, is particularly valuable to all engaged in agricultural and horticultural entomology, as well as to the general entomologist. Workers on this group of flies are extremely few throughout the world, and Mr. Barnes is doing good service in exploring the family so thoroughly. It may be mentioned that the present paper treats of the midges, the larvæ of which affect cereals, fodder crops, fruit, vegetables, and miscellaneous plants. It is the author's intention to supplement it later by additional parts dealing with the midges which attack trees and shrubs, together with others that are predaceous in habit and, therefore, beneticial. Copies of the paper under notice may be obtained at a charge of 3s/6d post-free from the author, Rothamsted Experimental Station, Harpenden, Herts

INVERTEBRATES FROM THE SPITSBERGEN BANKS. In an investigation into the bottom fauna of the banks around Spitsbergen, undertaken in the summer of 1925 and 1926 by the Tovik and Armauer Hansen, Dr. James A. Grieg gives an account of the invertebrates from the bottom, and the stomach contents-of certain fish eaught ("Evertebrater fra bankerne ved Spitsbergen indsamlet av Tovik og Armauer Hansen somrene 1925 og 1926. Fiskenaering og bundfauna." By James A. Grieg. Bergens Museum Aarbok, 1926. Naturvidenskabelig rackke Nr. 5). Besides a few smaller fishes the stomach contents of Gadus callarias, G. aeglefinus, and G. saida weve investigated, a long list of invertebrates being given for the two first mentioned, including many molluses, crustacea, echinoderms, and annelids. A photograph shows the contents of the stomach of a specimen of Gadus acylefinus, 75 cm long. This food weighed 675 grams and meludod 6 living Mya truncata (44-52 mm. long) and 4 dead (49-59 mm. long). In addition to these were several other molluses, Balanus shells, worms, echinoderms, and miscellanea. On the whole, the molluses, crustaceans, worms, and echinoderms seem to be eaten indiscriminately by both cod and haddock. The erab Hyas arancus is common. There were several with eggs, and it was found in numbers inside the cod. Hyas coarcticus, so far only recorded once before from Spitsbergen, also occurred. Pandalus borcalis was plentiful, bearing eggs in August. The bottom fauna of these regions consists of representatives of nearly all the large groups, including among the mollusca four species of Neptunea, the whole forming a good feeding ground for the fishes.

FISHING GEAR OF ENGLAND AND WALES. A revised edition of Mr. F. M. Davis's excellent account of the fishing gear of England and Wales has recently appeared. (Min. Agric. and Fish., Fish. Invest., Sor. 2, Sea Fish., vol. 9, No. 6, 1927. London: 11.M. Stationery Office. 5s. 6d.) Several additions have been made, including a description of the Danish plaice seine, or snurrevaud, and of such more recent forms of trawling appliances as the Vigneron-Dahl trawl, the Rowton 'stream line' trawl, and the French extenseur, which consists of a buoyant otter board to which is attached a heavy weight. The important experimental work carried out by Taylor and Wells in America and followed up by Atkins in Great Britain, on the use of copper elente as a net preservative, is also described. An enlarged bibliography, conveniently classified, includes references to accounts of foreign fishing gear and to a number of the more interesting historical treatises. The illustrations appear to be identical with those of the first edition, but their new arrangement as text figures inserted in appropriate positions has added considerably to their usefulness.

MUTATIONS IN HAPLOID DATURA.—The haploid Datura which was obtained by treatment with cold at the time of embryo-sac development has since been propagated by cuttings, and a completely homozygous  $\mathbf{F}_1$  has been obtained by self-pollination, as a few good pollen grains and eggs cells with twelve chromosomes are produced. Messes. Blakeslee, Morrison, and Avery (Jour. of Heredity, vol. 18, No. 5)

have studied the offspring of such plants and have obtained in the second generation a mutant in which the cotyledons have the peculiarity of being closely curled. The life cycle is otherwise normal. By crosses with trisomic (2n+1) forms, it is found that this gene mutation is in the same chromosome which produces the 'Poinsettia' type when present in triplicate. This chromosome also contains the factors for purple or white flower. There is therefore linkage between curled cotyledons and white flower, and the amount of crossing over between them is found to be about 12 5 per cent. Another mutant of even greater interest, from descendants of the haploid, is called 'tricarpel,' since the flowers have three or sometimes four carpels instead of the usual two. The other flower parts are correspondingly increased in number, the leaves are narrower, stems more slender and often triforked. The changes in the flower are really of generic value. The gene for this mutation is found to be in the chromosome which produces 'reduced' when present in triplicate The fact that these two mutations have appeared in the offspring of a necessarily homozygous haploid plant is emphasised as supporting the view that crossing is not necessary for the production of gene mutations. Their frequency (2.31 per cent. if two other unstudied mutants are included) indicates that the homozygous condition does not hinder occurrences of mutations.

PLANT GROWTH AND REACTION CHANGE IN CULTURE Solutions —Dr. Tsung-Lê-Loo records some interestmg experiments on the change of reaction in neutral salt solutions in contact with the root systems of living plants (Japanese Journal of Botany, vol 3, No. 3, 1927). The phenomenon was thought by previous workers (Czapek and Nathansohn) to be due to the excretion of acids or alkali by the roots The change in reaction is, however, too great to be ascribed to root excretion, and is now generally accounted for by the unbalanced absorption of amons and cations. In the present series of experiments, ammonium salts of morganic acids were used as the source of nitrogen, the experimental plants including Zea mais, Fagopyrum esculentum, and Oryza In contact with the roots of the culture plants the reaction of solutions containing ammonium nitrate, chloride, and sulphate respectively, became considerably acidic, the order of the change being from 1.3 to 1.8 of pH in two weeks. In the case of solutions containing sodium nitrate the reaction became more alkaline, the pH changing to a similar degree With ammonium monohydrogen phosphate and ammonium bicarbonate little change in reaction was noted. The increase in hydrogen ion concentration in solutions containing ammonium salts generally produced poor growth of the culture plants with the exception of paddy rice and buckwheat, which are evidently tolerant of an acidic medium. The slow and slight change in the case of phosphate solutions promoted favourable growth. A combination of two salts such as ammonium chloride and bicarbonate used as a source of nitrogen instead of a single salt, gave better results, and the fluctuation in growth ran parallel to the change in the reaction noted.

Sources of Underground Water.—Prof. J. W. Gregory, in a paper read to the recent summer meeting of the Institution of Water Engineers at Glasgow, combats the common view that all underground water is derived from percolating rain. He affirms that the plutonic water set free in the cooling of the earth's crust was sufficient to fill the oceans to their present level irrespective of meteoric water, and he sums up the position by saying that subterranean water comes from three sources—rainfall, which soaks

underground year by year, connate water, which is stored up in the beds at the time of their deposition, and plutonic water, which rises from the interior of the earth, and appears at the surface for the first time. This threefold origin complicates the distribution of subterranean water. Meteoric water, including both contemporary rainfall and connate water, is expected in permeable sedimentary rocks at depths not too great for the heat to debar the descent of water, or in which it is securely imprisoned, and though-joints, which may occur in rocks of any kind, may be used for storage, useful supplies of meteoric water are as a rule confined to sedimentary rocks or to vesicular igneous Plutonic water, on the other hand, may have a more varied distribution, for during its ascent it may force its way into any overlying rock which contains spaces available for water-storage.

Fossil Insects —Parts 8 and 9 of Dr. R. J Tillyard's series of papers on the Kansas Permian insects deal with the Copeognatha and Hemiptera (American Jour. Sci., 5, 11, 315, 381; 1926). The familiar forms of the Copeogratha are the wingless species known as 'book-lice' or 'cabinet-lice.' The geological record of this order is very imperfect Hitherto the only fossil forms known were found in the Oligocene (Baltic amber and Tertiary opal), but morphological evidence indicates that the order is an ancient one, and this has now been proved by the discovery of specimens, belonging to eight genera, in the Lower Permian of Kansas. These early forms, as might be expected, differ in many respects from their Oligocene and living descendants. The Hemiptera until recently were not known before the Lias, but during the last few years it has been shown that they were abundant in Australia in Triassic and Upper Permian times. Dr. Tillyard has now recognised four specimens in the Lower Permian of Kansas, and considers that they were derived from the more primitive forms of the Copeognatha. In a paper on the Upper Permian Insects of New South Wales (Proc. Linn. Soc. N. S. Wales, 51, 265; 1926), Dr. Tillyard describes new forms belonging to the orders Mecoptera, Paramecoptera, and Neuroptera. The remains of the case of a caddis larva from the Lower Eccene of Tennessee are described by Prof. E. W. Berry (Proc. U. S. Nat. Mus., 71, art. 14, 1926).

BITUMINOUS SANDS OF ALBERTA.—The Scientific and Industrial Research Council of Alberta has issued a report on the famous bituminous sands, by Messrs K. A. Clark and S. M. Blair, dealing mainly with the occurrence of these resources; two further reports are in course of preparation, one on the separation of bitumen from the sand, and the other on its utilisation. Although this report is well put together and contains much detailed information and good illustrations, we are rather at a loss to know why it should have been necessary to duplicate to such an extent the almost exhaustive work of S. C. Ells of the Mines Branch of the Canadian Department of Mines It was only a year ago that an excellent memoir by that author appeared, though according to the present authors their work was planned to supplement that of the Mines Branch at Ottawa. The whole problem of these bituminous sands is that of their commercial utilisation; as potential sources of bitumen for road-making and similar purposes, they are admittedly of great value, but until an effective and cheap method of separation is devised, they lose much of their economic attraction. It is gratifying to note, therefore, that the authors have given this phase of the subject their careful attention and that still further investigations in this direc-tion are in progress. They state that the hitherto inefficient method of hot-water separation has been developed to give very satisfactory results, which, in view of the cost of transporting the raw material, is important, since it means that the bitumen can be extracted at the source and dispatched within and without the Province as a marketable product. Herein lies a solution to at least one of the difficulties which have so far confronted commercial exploitation on a large scale, on the other hand, present industrial conditions may be unfavourable to extensive development, and any new stimulus, as Mr. Ells pointed out previously, may be somewhat artificial.

PHILIPPINE COAL RESOURCES.—In The Philippine Journal of Science for May 1927 there is a succinct but clearly drawn picture of coal mining in the Philippine Islands. It is pointed out that coal deposits exist practically all over the Islands, but that the deposits are small, patchy, and megular, the coal being either lignitic or sub-bituminous seams of coal are known, but only five are being worked, the thickness of the latter ranging from 30 cm. to about 4 m The author records 18 different localities at which coal is worked, and there appear to be very many others. Nevertheless, the total tounage of coal is estimated by him as only 21,200,000 tons, and the total production for the period 1842-1924 as 412,280 tons; only two localities have produced more than 100,000 tons within that period. The importation of coal during 1908–1924 has averaged close on 500,000 tons per annum. At present the local production does not exceed 50,000 tons per annum, and the author looks upon 100,000 tons as the probable limit It is, therefore, clear enough that the coal production of the Philippine Islands can have only a local interest.

THE HELIUM MOLECULE -- The substance He. appears to be more stable than has been supposed. It is still only known from its spectrum, and cannot be isolated, but W. Weizel and C. Fuchtbauer have succeeded in showing that the molecule is capable of performing inter-nuclear vibrations without dissociatmg. The measurements described by them in the Zeitschrift fur Physik of Aug. 16 are an extension of the earlier work of Prof. W. E. Curtis, but had to be made with powerful prism spectrometers, as the bands which have now been studied are very feeble new bands have been classified, eleven being of an orthohelium type, and two of a parholium type plates have not been examined with a photometer, but it is certain that transitions in which there is no change in the motion of the component atoms along their line of centres are much more frequent than transitions in which this occurs.

ELEMENT 61.—The isolation of the new rare earth element of atomic number 61 is the subject of an article by Dr. Hopkins in the Journal of the Franklin Institute for July. The circumstances which resulted in the discovery are related, and a further attempt is made to establish the priority of the American chemists and their right to name the element illinium. The presence of a new element was suspected during the course of some work on the red and infra-red regions of the spectra of neodymium and samarium which was carried out by the United States Bureau of Standards with the co-operation of the University of Illinois. This was due to the presence of 130 faint lines of unknown origin common to both spectra. The Bureau of Standards published these results in January 1922, whereas Prof. Rolla, who claims priority for himself and insists that the element must be called florentium, only began his work about that time. However, neither Hopkins nor Rolla published definite proof of the isolation of the element until last year. A useful bibliography is to be found at the end of the paper.

DISPOSAL OF LIQUOR EFFLUENTS FROM CLAS-WORKS The Gas Effluents Research Committee, appointed by the Institution of Gas Engineers in June 1926, has recently issued its first report. The purpose of the Committee was to investigate the methods which might be adopted for minimising the production of gas liquor effluents or for rendering such effluents suitable for running into town sewers or into rivers The report contains a memorandum on the disposal of liquor effluents from gas-works, which forms a summary of existing knowledge of the problem and the contributions which have so far been made towards its solution A list of important references is appended. A number of experiments of preliminary character have been carried out, and a short summary of the results is given. The disposal of effluents which result from the production of aminonia compounds is one of the most difficult parts of the whole problem. The constituents of the spent liquor include many which absorb oxygen and would unduly retard self-purification if admitted to streams and merease the difficulties of sewage purification if admitted to sewers in sufficiently large quantities. At the present time, however, the only satisfactory method of disposal appears to be the admixture of the spent gas liquor with sewage. It is necessary to provide means for adjusting the rate of admission in order to avoid large changes in the composition of the mixed sewage. In the meantime investigations are in progress with the view of reducing the volume and improving the composition of spent gas liquor resulting from gas-works practice.

STRESSES IN LARGE TURBO-GENERATORS. The SIZE of the turbines used by electrical engineers to drivetheir generators is steadily mereasing. In designing large turbo-generators which run at 3000 revolutions per minute, it is necessary to calculate the enormous centrifugal forces and the resulting strains to which the rotating parts are subjected. During recent years, due to their high speeds, there have been a few explosions of the rotating parts which have caused considerable damage. The question of safety therefore is one of the chief considerations. In the July and August bulletins of the Oerlikon Co. of Zurich, an interesting description is given of the precautions which are taken and the tests which are made to ensure safety. A very large factor of safety is allowed for in the design. Instead of having only an overspeed test in an explosion proof chamber, the Company subjects the completed machine to a series of tests. For example, a 3000 r.p.m. rotor is first run at 2500 r.p m. A special gauge then measures, with an almost incredible accuracy, after the temperatures have been equalised, whether there has been any permanent expansion. Tests are then made at 2900, 3200, 3400, and 3750 r.p.m., measurements being made after each If permanent expansion exceeding the permissible limits occurs, the rotor is rejected. Many further tests are made before the rotor is regarded as The question of the stresses during an accidental short-circuit' of the generator has also to be considered. A 30,000 kilowatt turbo-generator requires about 1000 cubic feet of air per second for cooling purposes. Ordinary air contains about 8 milligrams of dust per cubic yard. Hence even when good air filters are used, large quantities of dust collect in blind corners and the fans get elogged. To prevent this the closed circuit method is adopted in the Oerlikon machines. The same air continually flows through the generators, the ducts forming a closed circuit.

# An International Congress of Soil Science.

NTERNATIONAL meetings of scientific workers on soils have been held at intervals since 1909, when a small group met at Budapest. Eventually the International Society of Soil Science was formally constinational society of Soil Science was formally consti-tuted at Rome in May 1924. The new body held its first triennial Congress at Washington, D.C., on June 13-22, 1927, under the presidency of Dr. J. & Lipman, of Rutgers University, New Jersey. About four hundred delegates were present. Very extensive preparations were made by the American Organising Committee on which Dr. Shutt, Dominion chemist, and other Canadian representatives served Schreiner and Dr McCall, of the United States Bureau of Soils, were chairman and secretary respectively of the executive committee Thanks to the efforts of Dr Lipman, no less than 75,000 dollars was obtained in donations from various sources towards the cost of the Congress, and the subsequent tour of North America Some thirty nations accepted the invitation of the United States Government to send official delegates The largest unit—more than twenty delegates—came from Soviet Russia, Germany sent ten, and Great Britain seven Most of the countries within the British Empire were also represented.

President Coolidge honoured the Congress by attending the first session and delivering the opening address, in which he paid a tribute to European work on soils, and briefly traced the development of Federal expenditure on agricultural research from the modest initial grant of 1000 dollars in 1839 to the present day

For convenience in administration the Society is organised in national sections, but for its scientific activities is divided into the following ('ominissions, or Sections:

(1) Physics

(2) Chemistry

(3) Biology and biochemistry.

(4) Fertility.

(5) Classification, nomenclature, and mapping of

(6) Rural engineering and drainage.

These sections met both separately and jointly. Their work was much facilitated, first by the issue, on the opening day, of full abstracts in English, French, and German of all papers presented; and secondly, by the arrangement whereby the sections met independently at least once in the interval between the triennial conferences of the Society. Thus the Physics Commission met at Rothamsted in October 1926 to discuss the results of co-operative work on different methods of mechanical analysis of soil, airanged at the Rome meeting in 1924, and the Chemistry Section met at Groningen, Holland, in April 1926, to discuss soil acidity and methods of measurement. Difficult and doubtful points had therefore been fully examined before the Washington meeting, and one of the important tasks—securing uniformity in routine methods of analysis in the different countries-was appreciably lightened.

From the general body of papers presented a few main subjects may be selected for brief comment. Various forms of apparatus for mechanical analysis of soil continue to claim much attention, especially those types yielding data less affected by the serious errors, first noted by Coutts and Crowther at Rothamsted, that are inherent in the method of continuous weighing of the sediment Further, a clearer distinction is now being drawn between this form of mechanical analysis, that aims at giving a particle size distribution curve for the soil, of use in research work, and the more usual type of routine analysis, that divides the soil into a few groups of particles,

employed in the qualitative association of mechanical composition of soils with their field behaviour question whether this relationship can be made more definite by supplementing the mechanical analysis figures with other physical determinations, was examined from several viewpoints and was considered sufficiently interesting to be selected for the next co-operative investigation of the Physics Section.

The Chemistry Section was largely concerned with soil acidity and base exchange phenomena, and the newer physical-chemical methods of investigating the absorbing complex Prof Wiegner, of Zurich, made a notable contribution to this subject. Prof Bradfield, of Missouri, discussed the use of electro-dialysis in physico-chemical investigations of soils, a method that promises to be of great assistance in research work

The Soil Biology and Biochemistry meetings were exceptionally well organised in a series of symposia, which included (a) direct and cultural methods of soil microbiology: Winogradsky's direct counting method received much attention in this section; (b) the soil population; (c) nitrogen fixation in the soil: in the course of the prominent contribution made by Japanese workers to this section, the new technique of serum-reaction for the classification of Azotobacter was discussed by Prof. Ago and Prof. Yoshida; (d) transformation of organic matter in the soil: this section was perhaps of the most general interest, particularly the question whether organic matter originates from lignin or cellulose, which was discussed by Dr. Waksman of New Jersey, and Mr. H. J. Page of Rothamsted

In the Soil Fertility Section, additional examples of exceptional and abnormal soils were recorded, and the well-known work of the California Station on the growth of plants in culture solution and soil solutions

was further developed.

The discussion on classification, nomenclature, and mapping of soils aroused great interest, especially in view of the presence of Prof. K. Glinka, of Leningrad, the acknowledged leader in this field. The outstanding contribution to soil science in recent years is undoubtedly that of the Russian workers in recognising the predominant influence of climatic environment on soil formation, and the demonstration of the different types of soil by means of soil profile examinations. Up to the time of the Rome meeting, these studies had been confined largely to eastern Europe, but the papers presented at Washington were evidence of the advances that have been made in nearly every country in the past three years The sub-committees dealing with the soil map of Europe and of the Americas were able to report considerable progress.

Irrigation, drainage, and soil erosion problems occupied much of the attention of the sixth section, but time was reserved for a meeting with the Physics Section to discuss physical properties of soil and methods of measurement, including the dynamometer measurements of soil resistance made in the course of the Rothamsted work on the physics of soil cultivation, that have disclosed an unexpected degree of hetero-

geneity in apparently uniform soil.

During the Congress a number of addresses were given at general meetings by prominent representa-tives. Dr. Woods dealt with the origin and objects of the United States Bureau of Soils, and Dr. Baker with the trend of land utilisation in the United States; the present status of soil biology was discussed by Sir John Russell, Prof Lemmerman of Berlin, and Prof. 'Sigmond of Budapest, dealt respectively with soil acidity determination, and the chemical characteristics of soil teaching. The Russian delegates gave an account of soil work in their country in two sessions specially reserved for this purpose. This arrangement was much appreciated by the Congress, as it gave an opportunity for members to hear something of the extensive Russian work on soil science that, owing to its publication in Russian journals, has not hitherto been generally known

The American committee also staged a very successful exhibition, in charge of Dr. Weir and Mr. Goll, of the United States Department of Agriculture, arranged

in the following divisions

(a) Representative soil types of the world, showing characteristic soil profiles (in monoliths)

(b) Soil maps

(c) Methods and apparatus for physical and chemical work on soils.

(d) Soil fauna and flora, together with biochemical and biological apparatus

(e) A complete collection of United States soil science literature.

The exhibition was by far the most complete one yet brought together, and its interest was enhanced by the inclusion of much of the apparatus and initerial discussed at the meetings of the Congress. It is the intention of the Committee to retain the monoliths of representative soil types as the basis of a permanent collection of the soils of the world.

At the conclusion of the Congress, the delegates joined a special train for a thirty-days' tour of the most important agricultural regions and soil belts of North America. Foreign delegates were the guests of the American Organising Committee during this tour. The route selected ran through the cotton belt, across

the southern portion of the Prairie and the Great Plain to the irrigated area in Utah, and thence across the desert to the irrigated region in South California. The return journey was made through California, Oregon, and Washington to Vancouver, and thence by the Canadian National Railway through Alberta and Saskatchewan to Winnipeg The tour then re-entered the United States, traversing the north and eastern sections of the Pranie before returning from Chicago to Washington, via Indiana, Ohio, and West Virginia. Many stops were made en route for the inspection of profiles typical of the local soils. This portion of the programme was arranged by Dr. Marbut, Chief of the United States Soil Survey, and his explanations of the various teatures in which some of the American soil types differed from the European soils on which climatic classification was initially based were of extreme value to European workers. Excursions were arranged at numerous points to see experimental stations, the local agriculture and objects of general interest.

A striking feature of these numerous trips was the generosity of organisations such as chambers of commerce, that arranged motor-cars for transportation, and provided meals for the whole party. It was evident, not only from the speeches of welcome at local centres, but also from informal talks with farmers and others, that the greatest interest was shown in the aim and objects of the Society; the bulk of this can be directly traced to the general appreciation of the work of the United States Federal and State agricultural services, and the consequent recognition by both the rural and urban population of the fundamental importance to the country of a vigorous agricultural life.

B. A. Keen

## A New Journal of Forestry.

SOME articles of considerable importance and interest appear in the first number of the new journal, Forestry. The number opens with an article on "British Forestry," by Mr. R. L. Robinson, a Forestry Commissioner. Much of this has appeared m the last report of the Forestry Commission, which has been already discussed in NATURE. It is rather of the nature of propaganda for the public than a technical treatise, for all British foresters will be acquainted with the position the writer depicts. Mr. H. M. Steven, the editor, follows with a lengthy paper on the "Silviculture of Coniters in Great Britain." This, and a companion article on the "Silviculture of Hardwoods in Great Britain," by Mr. W. II. Guillebaud, are of high intrinsic value. In these papers the past history of the principal tree species of Great Britain to the present day are traced, the methods by which they have been grown, and the ills which have so generally resulted in latter times from these methods. The historical data which Mr Steven gives on the subject of the Scots pine and the European larch, amongst other species, and Mr. Guillebaud's remarks on the oak and beech high forest, are well worthy of careful attention. If a word of caution is required, it may be confined to a necessary recognition that research and experiments based solely on the work of the past ten years should not be awarded, in the case of forestry, too great a prominence; for definite data will only be attainable at the end of a rotation, and in some cases possibly not even then.

The succeeding two articles on the "Utilisation of Soft Woods in Great Britain," by Mr. John T. Smith, chiefly dealing with Scotland, and the "Marketing

\*\* \*I Forestry The Journal of the Society of Foresters of Great Britain, vol. 1, No. 1 (1927), 7s. 6d

of British Hardwoods," by Mr. J. H. Newnham (Acorn), deal with the commercial aspects of forestry. There is little new in the articles, but the treatment of their subjects by the writers is not without interest to the professional forester, and some of the problems pointed out will need and are receiving eareful attention. Nor do the remedies all fall within the scope of the forestor. If the landowner of the future wishes to realise any return from the portion of his estate maintained under woodlands, he will have to adopt very different and drastic methods. The surest and the best will be to imitate some of his brother proprietors of land in France and learn how to manage his woods on sylvicultural lines himself. Unless the land tenure systems of Great Britain undergo a radical change, the country will not be able to depend, or afford to depend, solely on the efforts of the Forestry Commission for its tumber requirements. In no country in Europe are the forests in sole State ownership In the view of some experts the encouragement of the private owner to introduce a correct administration into his woodlands should form one of the chief objects of the Commission.

Major F. M. Oliphant deals with the manguration of the new "Forest Products Research in Great Britam," and describes the various sections of the work to be undertaken; whilst Mr W. Dallimore considers, in the lighter vein, the aesthetic side of afforestation, voicing opinions which have received attention in the press on the subject of the ugly uniformity of "huge blocks of pines... the trees spaced with mathematical accuracy and only relieved by other blocks of another kind of dismal uninteresting tree." The writer's suggestions merit considera-

No. 3019, Vol. 1201

tion, especially the hope that all England's hedgerow trees and clumps and so forth are not doomed to

disappear.

Omitting several other technical articles, reference may be made to four papers from a foreign source. These are: "A General Review of Post-War Forestry ın Central Europe," by Dr. Ing. Franz Heske; "Some Recent Forest Research in Norway," by Erling Eide; "Recent Forest Literature in Denmark," by Carl Mar Møller; and "Forest Research in Finland," by Lauri Ilvessalo. Space will not permit a consideration of these papers, but the first calls for a brief remark. "The War and its consequences," says Dr. Fianz Heske, "have changed Central Europe in many important points Forestry being a welldeveloped and most essential part of the economic life in the respective countries, naturally could not escape the great transformations which have taken place" The writer deals with the changed conditions in Germany and the old Austrian monarchy. Immediately after the War, it appeared that forest policy and political conditions were the two items which required the most urgent revision however, says the writer, the problems of reform in sylviculture and management came more and more to the front, and the question of increasing the productivity of forestry became dominant He contends that these two directions of evolution can be clearly distinguished in the German countries, whereas in others, eq Czecho-Slovakia, political reforms have so far remained the chief interest. In this extremely interesting paper the author depicts the pre-War conditions of his subject and then deals with the post-War ones, as at present envisaged. The article is not, however, complete It is "To be continued" Since at present the journal is only to appear once a year, it is a pity that the whole could not have been included.

Reviews of some seven books are dealt with This is the weakest section of the journal. A far larger series of important forest publications could have found a place within the space allotted it some of the reviews included had been drastically cut down. If the high efficiency with which Forestry has been started can be maintained, all foresters in Great Britain should welcome and value such a professional journal.

# The Danish Lobster Fishery.

MR. ERIK M. POULSEN has published an interesting survey of the Danish lobster fishery compared with that of Norway, Sweden, and other countries ("Om Hummeren og Hummerfiskeriet i de Danske Farvande" Skrifter udgivne af Kommissionen for Danmarks Fiskeri—og Havundersøgelser No. 10 Copenhagen, 1927). Lobsters in the Danish seas are found along the coast from a depth of a few metres to about 40 metres, on a stony or gravelly bottom They are commonest on a stony bottom such as is found in the Northern Kattegat and Jammerbugton. Below a depth of about 40 metres they rarely occur, being replaced in the deeper waters down to about 300 metres by the Norway lobster (Nephrops norvegicus). The scarcity of newly hatched young in the upper water layers is remarkable, the author attributing this fact to the probable natural habitat being near the bottom even in the free-swimming stages, and after the third moult it apparently lives actually on the bottom.

Lobsters from the Danish Skaggerak coast are not merely larger than those from the Kattegat, but they are also distinctly larger than those from the Norwegian and Swedish Skaggerak coast as well as from the south-west coast of Norway. The reason for this attributed to the difference of salimity and temperature, a high salimity and high temperature being

agreeable to the lobster, a low salmity setting a limit to its distribution

Marking experiments by the method used by Appelhof in Norway and Tryboin in Sweden were undertaken, small triangular pieces being cut away from the edge of the telson and tail fin which were easily recognisable. In this way even if the skin be cast the cuts are still visible Out of one lot of 200 lobsters set free, only one made a long journey, nearly ten sea-miles; the others only went about one to three sea-miles. In a different lot a few journeyed ten to fifteen sea-miles. They are inclined to pass the summer in shallow water and the winter in deeper water, and this applies not only to the breeding females but also to others of a certain size which seem to need different conditions in the summer The abundance of food in the shallower waters near the coast seems obviously an advantage for the newly hatched The author does not mention the hatching and rearing experiments made at Port Erin, Isle of Man, which prove conclusively that the newly hatched lobsters, and also those in the first tew stages, feed on small planktonic organisms, especially copepods.

Interesting notes are given on the methods of catching lobsters, traps being chiefly used, the bait being flat fishes (plaice and dabs), small haddock, and fishing-frogs.

# University and Educational Intelligence.

OXFORD—The new Rockefeller School of Biochemistry will be opened by the Lord Chancellor, Viscount Cave, on Friday, Oct. 21, at 3 30 Pm.

THE City and Guilds of London Institute has received from the Corporation and City companies since its foundation forty-seven years ago contributions amounting to £1,156,094. Its report for the year 1926 deals with the affairs of the City and Guilds (Engineering) College, the Finsbury Technical College (finally closed in July 1926), the South London Technical Art School and the Department of Tech-The first-mentioned college was in 1907 merged in the Imperial College of Science and Technology, but the Institute continues to contribute to the cost of its maintenance. Of the two thousand degrees in engineering awarded by the University of London since 1903, nearly half have been won by students of this College. In 1926, for the first time, the degree was awarded on the College examinations, and the results show, says the Dean, that there is very little difference between the standards under the new and the old system, and he concludes that "whatever system of examination be applied to young men, provided they are properly trained, the result is substantially the same "The Department of Technology examined 13,985 candidates for its certificates, including 1788 at places outside the British Isles. The report suggests a doubt as to whether the movement in tayour of demanding a more definite knowledge of elementary science (especially physics and chemistry) as forming the ground work of the main technical subject, has not been pressed too far.

That the teacher should never cease to be a student is, perhaps, a platitude. In few places, however, are there such opportunities for the teacher-student as are available in London. Lectures and classes for teachers, specially arranged by the London County Council, make it easy not only to follow up special subjects, but also to obtain a view of the wider background which gives significance to those subjects. Facilities are provided at fees which average less than 1s. per lecture for any one engaged in teaching in London, Kent, or Middlesex (other teachers are admitted at fees 50 per cent. higher),

and are designed to bring London teachers into touch with the latest developments in educational methods and to enable them to hear leading authorities on current questions of importance The recently published Handbook to the Lectures for 1927-28 contains details of arrangements made to cover a vast number of subjects. In the science section are courses of lectures and lecture demonstrations on the application of physics to everyday life, light, with special reference to artificial light and its measurement; the Science Museum (intended to give a fuller acquaintance with the contents of certain of the Museum's engineering collections), science for elementary schools and for guls' schools, nature study, with special reference to the open spaces in and near London; nature study in infants' schools By the courtesy of certain scientific societies, provision is also made for the disposal by the L C C. of a number of tickets of admission to their ordinary meetings Domestic and health subjects include a single lecture on sunlight and health, and ten lectures on dietaries in relation to health. The geography section includes a course dealing with the relation between geography and agriculture. Experimental psychology and its bearing on education is to occupy five lectures Particularly important is a course on modern thought and education, the purpose of which will be to consider the background of instructive ideas which controls the activities of this generation and is expressed in the contemporary attitude towards education. In most cases the Handbook gives, in connexion with the courses, lists of books recommended for study.

EDUCATIONAL Boards and Foundations in the Umted States are described in Bulletin, 1927, No 10 of the Bureau of Education. The General Education Board has, since its foundation in 1902, appropriated 137 million dollars for the promotion of education in the United States. For the year 1925-26 appropriations amounted to 15 million dollars, half from principal and half from income. The Rocketeller Foundation spent 9 million dollars on health projects and medical education, including expenditure through its International Health Board and China Medical Board. The Laura Spelman Rockefeller Memorial appropriated for educational, charitable, and scientific purposes nearly 8 million dollars, including nearly one million dollars for the promotion of child study and parental education. The Carnegie Corporation of New York made grants amounting to 6 million dollars, of which more than 41 million dollars went to library service, 600,000 dollars to activities in the fine arts, and 300,000 dollars to the newly formed move-ment for adult education. The Carnegie Foundation for the Advancement of Teaching disposed of an meome of  $1\frac{1}{3}$  million dollars, devoted mainly to retiring allowances and pensions. Other important foundations described are the John F. Slater Fund for teacher training and other schools in the Southern States; the Jeanes Fund for the improvement of negro rural schools; the Phelps-Stokes Fund for improving New York slums and the education of negroes, Indians, and needy whites; the American Field Service Fellowships for French Universities; the Belgian Fondation Universitaire; the Julius Rosenwald Fund for charitable, scientific, educational, and religious purposes; the Baron de Hirsch Fund for aiding Jewish immigrants; the Kahn Foundation for foreign travel of teachers; the Commonwealth Fund for child welfare, rural hospitals, and education; and the Engineering Economics Foundation. The Commonwealth Fund maintains 23 fellowships, amounting to 125,000 dollars, for graduates of British universities for two years' study in American universities. Three are earmarked for British overseas dominions students.

# Calendar of Discovery and Invention.

September II, 1822—Copernicus asserted the daily rotation of the earth on its axis, and showed that it accounted for the apparent diurnal revolution of the stars. He also showed that most of the known motions of the planets could be explained by assuming them to revolve round the sun, with the earth as one of them. The teaching of the Copernican theory was torbidden by the Church in 1615—On Sept. 11, 1822, the Pope repealed this decree, and permitted the Copernican views to be taught—nearly three hundred years after they were first published.

September 12, 1891. A scheme for the electrical transmission of power on the three-phase system from Lauffen to Frankfurt a M in Germany was prepared by Michael von Dohvo-Dobrowolsky; the system was erected and put into operation on Sept. 12, 1891. The distance covered was 175 km, three copper wires of 4 mm diameter being used. The alternator voltage was 55, and this was raised by transformers to 8500. The efficiency of transmission was 74 per cent.

September 13, 1850. After years of labour, the engineers lowered the last of the tubes of the Britannia Bridge, over the Menai Straits, to its permanent resting-place on Sept 13, 1850. The bridge has two spans of 460 ft, and two of 230 ft., at 104 ft. above high water. The official return of the cost was £601,865.

September 14, 1899 — The Times of this date reports that "for some weeks past experiments of great interest in wireless telephony, as distinguished from Signor Marconi's wireless telegraphy, have been carried on by Sir William Precee near Carnarvon. Sir William has succeeded, without any intermediary other than the ether, in transmitting the sound of a series of taps. . . . They were distinctly heard at the receiving station by placing the newly invented ethereal telephone to the ear. . . . So far, it is stated, the system yields much more rapid results than Marconi's, although the sounds are not quite so distinct as desirable."

September 15, 1830. A number of routes for a railway between Liverpool and Manchester had been proposed and surveyed before a final scheme was authorised in 1826. George Stevenson was the engineer, and the line, which was 31 miles in length, was opened for public traffic on Sept. 15, 1830. In 1845 it was amalgamated with the Grand Junction Railway, and in the following year these became part of the London and North-Western system. The gauge was 4 ft. 8 5 m., and the ruling gradient 1 in 89. There were 63 bridges on the line

September 16, 1911.—Edward Whymper is most popularly associated with the tragic first ascent of the Matterhorn in 1865. He was the pioneer climber of many other peaks of the Alps, the Andes, and the Rockies. More than a successful mountaineer, he was a keen observer of geological phenomena, a student of glaciers, a first-rate collector, and a good woodengraver. He died suddenly at Chamonix on Sept. 16, 1911. A plaque to his memory was unveiled at Zermatt in 1925.

September 17, 1607.— Thomas Harriott first saw the comet of 1607 (Halley's) from Ilfracombe on Sept. 17. He made observations upon it with a 'cross-staff,' giving the distances of the nucleus from the various stars. Harriott had been to Virginia as a surveyor with Sir Richard Grenville's expedition in 1585. He virtually gave to algebra its modern form, and applied the telescope to celestial purposes almost simultaneously with Galileo. With its help he studied the moon, "the new-found planets about Jupiter," and sunspots.

W. C.

### Societies and Academies.

#### PARIS.

Academy of Sciences, Aug. 1.—A. Lacroix The composition and structure of the meteoric iron of Tamentit. The oxidation of meteoric iron at a high temperature. Analyses gave iron 91 per cent., nickel 8 per cent, cobalt 0.38 per cent, with some manganese, phosphorus, sulphur, carbon, and silicon The meteorite weighed 510 kilograms, and a piece was cut off by means of the oxyacetylene blowpipe. Analyses of the magnetic oxide produced showed it to be free from nickel, and the metal fragments taken from the scoria showed a concentration of the nickel. bearing of this on the composition of meteorites containing silicates is discussed.—F. E. Fournier Thesistance of water to the translation of hulls-Gabriel Bertrand and Hirosi Nakamura: The physiological importance of nickel and cobalt. In an earlier communication (Bertrand and Machebœuf) it has been shown that traces of nickel and cobalt are normal constituents of man and of animals. Experiments on mice suggest that these two metals have a direct action in nutrition .- d'Arsonval: The heating of the tissues by high frequency currents The thermal ammeter is generally employed to measure the strength of the currents used; but it is not a trustworthy guide when used as a measure of the heating of the tissue under treatment.—Léon Guillet, de Fleury, and Sensaud de Lavaud The aluminium-silicon alloy known as 'alpax': its applications Mechanical properties of the alloy cast at 575° and 775° C, after addition of sodium. It can be used in the construction of motor-car chassis.—G. Friedel: Forms assumed by myeline in contact with water.—Amé
Pictet and H Vogel The synthesis of lactose. Equal weights of  $\beta$ -galactose and  $\beta$ -glucose, with a little zinc chloride, are heated under reduced pressure to 175° C. That lactose was obtained was proved by its melting point, solubility, and rotation. The osazone, nitrate, and acetate were prepared.—Charles Nicolle, Charles Anderson, and Jacques Colas-Belcour: A new pathogenic spirochæte (Sp. Normandi) transmitted by an Ornithodorus (Orn Normandi).—Krawtchouk The poles of analytical functions.—C. Irañez de Irero: A submanne link between Spain and Morocco, by means of an intercontinental tunnel. A tunnel across the narrowest part of the Straits would be impossible, as there are depths of more than 900 metres. A possible line is sketched out which would have a length of 48 2 kilometres, of which 32 kilometres would be under the sea.—F. Gonseth and G. Juvet: The equations of electromagnetism —James Basset: An apparatus for carrying out physical or chemical experiments at varying temperatures and under pressures of 15,000 kilograms per square centimetre. The description is accompanied with photograph and sectional drawing of the apparatus.—B. Cabrera The theory of paramagnetism.—Armand de Gramont. Monostatic telemetry during twilight -R. de Mallemann and P. Gabiano: The circular dichroism of the alkaline cuprotartrates.—Lucien Mallet: The luminescence phenomena in the course of oxidising reactions m aqueous solutions. During the oxidation with alkaline hypochlorite of various organic substances (albumen, methylene blue, eosin, quinine, etc.) light is produced. The intensity is increased when the temperature is raised.—Eugène Delauney: A new method of quantitative analysis applicable to a mixture of rare earths. The method is based on the measurement of the thickness of an absorption band, \_as shown in a small Hilger spectrograph. Various examples of the use of the method are given.—W.

Ipatieff and J. Andrewski The precipitation of ridum and its solutions by hydrogen under pressure. At temperatures of 100° and 103° C the proportion of iridium reduced by hydrogen has been studied for pressures between 1 and 10 atmospheres The reduction increases with the dilution, with the pressure of the hydrogen and with the time of exposure. The general results are very similar to those previously obtained with platinum.—Dedebant: The field of instantaneous displacement of isobars.—Mlle. M. Gauthier · The French larvæ of Ephemerids referred to the genus Iron -F. Mercier and Raymond-Hamet: The vaso-constrictive action of hydrastine —Mme. L. Random and Mlle A. Michaux The variations in the proportions of iron in the liver, the spleen, and the blood, under the influence of feeding in the complete absence of the antiscorbutic vitamin.—Raoul M. May: Microchemical studies on the nervous system. The proportion of sulphur and phosphorus in the cerebral hemispheres of the guinea-pig.— Charles Lebailly · The preventive and specific vaccination of dogs against distemper.

Aug 8.—The president announced the death of Emile Schwoerer, correspondant for the section of mechanics. -Charles Nicolle and Charles Anderson: The transmission of the spirochæte of the shrew mouse by Ornithodorus moubata and the mechanism of the transmission of recurrent spirochetes by ticks.—S. Finikoff: Stratifiable congruences —Pierre Dive: The most general internal movements of a heterogeneous fluid mass in rotation round an axis.—Louis de Broglie The rôle of the continuous  $\psi$  waves in undulatory mechanics Maurice Lambrey: The absorption and emission spectrum of nitric oxide in the ultra-violet. Nitric oxide has been considered as completely transparent, but has now been found to have absorption bands in the ultra-violet. The same lines were found in the spectrum given by the gas in discharge without electrodes. Carbon monoxide was also found to give a fine absorption band in the same region.—René Dubrisay and Jean Bravard: The influence of absorbent materials on chemical equilibria in solution. In the reaction between ammonium chloride and calcium carbonate in aqueous solution, the equilibrium is displaced by the addition of absorbent substances, such as kieselguhr, sand, precipitated silica, clay, and kaolin.—Emile André and Mile. Th. François: The study of oleilic alcohol and its derivatives. Preparation of oleicerine, elaidicerine, and stearolylic alcohol. -J. Dugué: Modifications of methods and of treatments resulting from the application of the theory of antioxygens. Discussion of the preparation of indiarubber from the point of view of the antioxygen theory.—R. Abrard, L. Joleaud, and Paul Lemoine: The conditions of the deposit of the Montian of Port-Marly (Seine-et-Oise).—E. Rothé, J. Lacoste, and Mlle Y. Dammann: Earthquakes in France in 1926. Fifteen well-characterised earthquakes were felt in France during 1926. The Pyrenees region and the Central Plateau were more stable than in preceding years; the most important phenomena affected Alsace and the Channel coasts.—Henri Humbert. A new Composite remarkable from the phylogenic point of view, *Tisserantia africana*.—A. Lebediantzef. The modifications of the solubility of the phosphoric acid and the biological properties of the soil observed in earth lying fallow and previously dried in the open air—A. Th. Schlæsing: Remarks on the preceding communication.—Edouard Chatton and Mme. M. Chatton: The conditions necessary for determining experimentally the conjugation of the Infusoria Glaucoma scintillans.—F. Viès and A. de Coulon: The experimental modifications of the receptivity

index of mice for grafts of tumours—George F Jaubert. The origin of the yellow colour of beeswax—Weinberg and J Barotte. Researches on antitoxic and antimicrobial sera.

#### SYDNEY

Royal Society of New South Wales, July 6 - J. W. Fielding · Observations on rodents and their parasites The author examined 222 rats collected alive at Townsville, N Queensland, for ectoparasites. them he found 536 fleas, of which 493 were Xenopsylla cheopis, 33 Ctenocephalus felis, 8 Ctenocephalus canis, 1 Pulex irritans, and 1 Ctenopsylla musculi Two were covered with an undetermined genus and species of mite Data as to leprosy in rats, and also the presence of Trypanosoma lewisi, Leptospera icterohæmorrhagica, Eimeria sp. and worms were given —The late Sydney Dodd · Swelled head in merino rams Although the almost invariably fatal condition known among sheepowners as 'swelled head' is generally regarded as affecting only young merino rams, it also occasionally affects older sheep. The condition has been ascribed from time to time to a number of different causes, including plant poisoning and streptococcic infection A bacillus has been found in the adematous fluid of the face, in the tissues of the affected muscles of the head and in the heart's blood during post-mortem examinations made immediately after death on typical cases. Experimental inoculation of pure cultures of this bacıllus into the leg of a sheep produced lesions similar to those met with in cases naturally The organism is anærobic and shows evidence of gas formation with dissociation of muscular tissue, but not particularly of a rancid nature -W. F. Blakely: Descriptions of nine new species of Eucalyptus Five of these belong to the Stringybark group, two to the Peppermint group, one is Ash, and one Bloodwood. Eight are indigenous to New South Wales, and one to the Northern Territory -- A. R. Penfold: The essential oil of Eucalyptus Bakeri This pendulous willow-like tree of 30 ft.-50 ft. in height has a range from northern New South Wales to central Queensland. The principal constituents of its oil are cineol (70-77 per cent.), cymene, the aromatic aldehydes (cuminal, phellandral, cryptal), phloracetophenone-dimethyl other and the esters (isobutyric, isovaleric, and formic) of cuminol and phollandrol. Australol (p-isopropyl phenol) d-a-pinene and Australol (p-isopropyl phenol) d-a-pinene and sesquiterpene alcohol were also present in small quantities.

#### WASHINGTON, DC.

National Academy of Sciences (*Proc.*, Vol. 13, No. 6, June).—H. Walter Leavitt and John W. Gowen Mineralogical content of Maine sands in relation to mortar strength. The percentage of granitic material in the sand plotted against the tensile strength after 7 days and 28 days setting, shows that strength decreases with increase of granitic material; thus quartz sand is not the best for making strong concrete Increased strength goes with increased iron content and the latter with decreased granitic content, but there is also an independent effect of iron.—Dickinson W. Richards, Jr.: On the mechanics of blood flow, with special reference to the influence of change of posture. On changing from recumbancy to the standing posture, blood pressure increases and the volume of blood flow decreases in man. Applying Poisseuille's law of flow of a viscous liquid in a cylindrical tube, it is suggested that the changes are associated principally with arterial construction.—Francis G. Benedict and Cornelia Golay Benedict: The nature of the insensible perspiration. The subject

hes on the balance and breathes into a closed circuit respiratory apparatus also on the balance weight then measures the loss through the skin (chiefly water), and it averages 50 per cent. of the total loss The total msensible loss of a woman is 20 gm.-30 gm per hour, that of a man is nearer 40 gm per hour. Of this, about 45 per cent is water from the skin, about 45 per cent is water from the lungs, and 10 per cent. is the difference between oxygen mtake and carbon dioxide output The temperature of the environment and clothing make little difference The total insensible loss is a good index of the total metabolism. - A M Showalter · Hermaphroditism in a directous Hepatic Raoul M. May. Modifications of nerve centies due to the transplantation of the eye and olfactory organ in anuran embryos. The grafts develop synchronously with the corresponding organs of the host. There is at first. marked affinity between the optic neuroblasts and those of the central nervous system (neuroblastotropism). The pia mater is only penetrated with difficulty by axons from the grafts. Samuel F. Hildebrand and Charles Hatsel. On the growth, care, and behaviour of loggerhead turtles in captivity. The incubation period for the eggs appears to be-64 days, and the young remained at the surface of the water in the aquarium. Even when grown, they are sensitive to cold. Two specimens reared from eggs were kept for six years, their food being mainly fish, with occasional blue crabs and hard clams. Their weights when released were 55 lb. and 61 lb -William Albert Noyes: (1) Magnetic hydrogen atoms and non-magnetic molecules. Suppose that under the catalytic effect of a metal, the orbits of the electrons of loosely joined hydrogen atoms are made to take opposite directions: the electrons are held by their nuclei but fall closer because there are now tweenuclei instead of one. This might account for the dissipation of energy when the molecule for is. (2) The relation of the octet of electrons to consacton. Close approach of atoms, molecules, or ions in solution involves strong repulsion between the external shells of electrons, leading to elastic collisions in which the components maintain their independent existence after collision. Edison Pettit: Ultra-violet solar radiation. Two quartz cells, each consisting of a lens and plate, one silvered and the other gilded on the inner surfaces, are mounted at opposite ends of a diameter of a disc. The disc is carried by a spindle operated by an escapement so that an image of the sun formed by the silvered cell falls in turn on the junctions of a compensated thermocouple, after which the same procedure is carried out with the gilded cell. The galvanometer deflexions are recorded photographically and give the ratio of ultra-violet to green radiation every four minutes. The green radiation remains fairly constant, whereas the ultra-violet is zero for some time after sumrise and reaches a maximum at noon. The monthly mean of the ultraviolet radiation follows roughly the solar constant and the Mount Wilson daily sunspot numbers, but runs counter to the atmospheric ozone curve -B. P. Gerasmovič and W. J. Luyten. On the distance of the sun from the galactic plane. The mean elevation of the sun above the galactic plane defined by the Cepheid variables, the O, B, and c and ac stars is +33 parsecs, with a mean error of not more than 3 parsecs—Walter S. Adams and Alfred II. Joy: (1) The relationship of spectral type to period among variable stars. There is a practically linear correlation between spectral type and logarithm of period of light variation for the best known Copheids. Long period variables and the mean for short period cluster type. variables fall nearly on the Cepheid curve. (2) Highdispersion stellar spectra and some results of a study of  $\gamma$  Cygni. A spectrograph of 15 ft focal length and 6 m. aperture has been installed with the 100 m. reflector at Mount Wilson, the linear scale of the spectrographs obtained is about 2.9 ÅU to the millimetre at Hγ. Lines of rare earths have been identified in the spectra of γ Cygni and those of Ce<sup>+</sup> show a systematic displacement, possibly caused by relative upward motion of the gases where they originate -M S. Knebelman · Groups of collineations m a space of paths -P. Ehrenfest and P. S Epstein Remarks on the quantum theory of diffraction-Richard M. Badger Absolute intensities in the Absolute intensities in the hydrogen chloride rotation spectrum The probabilities of transition from the initial to the final state with absorption of radiation are calculated from integral absorption coefficients, but the experimental results are not in agreement with the predicted values. -R.B. Lindsay: Note on 'pendulum' orbits matomic models The 'pendulum' orbit involves the notion of an electron penetrating the nucleus This may be avoided by assuming a repulsive force in the neighbourhood of the nucleus Assuming this obeys an inverse cube law, reasonable values of the effective radius of the nucleus are obtained -Bergen Davis and Harris Purks Measurement of the Mo  $\check{K}$  doublet distances by means of the double X-ray spectrometer. One crystal is mounted as usual on the spectrometer table and a second crystal is carried on a rotating arm; radiation is reflected from the first to the second and thence to the ionisation chamber The angle through which the second crystal is turned is twice the difference between the angles for reflection of two The results are closely independent of horizontal slit width, so that it is possible to have sufficient intensity of radiation to permit accurate measurements—J. C Slater: The structure of the helium atom (1). A method is developed of obtaining an approximate solution to the problem of calculating the spectrum of helium from the wave equation of mechanics. It can also be applied to yield qualitative results with higher atoms and molecular structure.— Walter A. MacNair: The Zeeman effect of the hyperfine structure components of  $\lambda$  2537 of mercury. Each of the five lines found by Wood has a triplet Zeeman pattern.—Paul S. Epstein. The dielectric constant of atomic hydrogen in undulatory mechanics. For the excited states of the atom, in weak fields the orientation is arbitrary; in strong fields this is not so. Owing to the complete symmetry of the atom in the normal state, the question of orientation is here without meaning—Evelyn F Aylesworth. The discertic constant of atomic hydrogen from the point of view of Bohr's quantum theory. The calculations lead to results similar to those recorded in Epstein's paper above.—David L. Webster: Direct and indirect production of characteristic X-rays Indirect rays will be produced at depths in the target averaging more than the mean depth of rays producing the continuous spectrum. With a target of silver 25 microns thick plated with copper, the majority of the K-radiation is direct when the cathode rays are driven by a steady voltage of 35 kv., d.c. Other targets used were blocks of cadmium with one or two sheets of silver foil 6 microns thick and a block of graphite plated with silver 3 5 microns thick. With 50 kv., the ratio of the direct to the indirect rays was 2.36.— Carl Barus: Mucronate electrode with micrometer.— Carl Eckart: The reflection of electrons from crystals. Electron reflection differs from X-ray reflection in that a single plane of atoms reflects an appreciable fraction of the electrons and that the wave-length of the electron wave inside the crystal differs from its wave-length in free space.—Edward Uhler Condon.

(1) Coupling of electronic and nuclear motions in diatomic molecules (2) Wave mechanics and the normal state of the hydrogen molecule. A discussion based on the quantum theory of the binding of atoms mto molecules (valency forces) gives results in fair accord with experiment.—Gilbert N. Lewis A new equation for the distribution of radiant energy-C. F. Richter. The hydrogen atom with a spinning electron in wave mechanics. It is claimed that the fine structure of hydrogen-like spectra can be represented completely by the Schrodinger wave mechanics with the Uhlenbeck-Goudsmit spinning electron

# The Imperial Agricultural Research Conference.

REAT BRITAIN is an industrial country; but the British Empire, of which it is the head and centre, is an Empire of agriculture, and of extraordinarily various agriculture conducted under extraordinarily various conditions sight there is little in common between the production of wheat, livestock, or fruit in England and the great Dominions, the growing of rubber in Malaya, of the oil-palm or ground-nut in India and West Africa, and of the sugar-cane or banana m the West Indies. But in truth all crop- or fruitgrowing and all livestock husbandry rest on the same fundamental principles, though their application may present a very different problem in different countries, and therefore all agriculture has at least one common interest—the elucidation of those principles

The Imperial Agricultural Research Conference, which is to meet in London at the beginning of October, will be primarily an attempt to survey and organise the scientific resources of the Empire for the increase of agricultural knowledge. Research has two main requirements—first (a long way first), trained men; and second, equipment. In both these requirements the Empire is, broadly speaking, far below the needs of the work to be done and the problems demanding a solutionproblems not of purely scientific interest but of immediate importance for the prosperity, and almost for the existence, of large populations. In Great Britain it is true that we possess, thanks mainly to Sir Daniel Hall, a coherent organisation of agricultural research institutes, reasonably staffed and equipped But outside Great Britain, and with a few exceptions, such as the Animal Diseases Station which Sir A. Theiler has established in South Africa, agricultural research, where it exists at all in any sense worthy of the name, is sporadic, ill-equipped, and un-organised. Yet in the tropical and sub-tropical colonies alone (without including the Dominions and India) there are something more than 2,000,000 square miles, and 50,000,000 people practically all dependent on agriculture of one kind or another.

No conference can provide men or money Money, however, is now available to some extent from the Empire Marketing Board, which is devoting to the encouragement of agricultural research a not insignificant proportion of its income; the provision of trained men is a matter of time, the offer of a career, and personal inspiration.

But the conference which meets in October can and will attempt to answer the question, "How can the different parts of the Empire best help one another in their common aim, the advancement of agricultural science?"

To those familiar with any kind of research, this general heading will suggest many specific problems. First and most important of all, there is the recruitment and training of research workers. It is well known that while in some branches of science there is a fair supply of young men coming forward to take up research, m others there is a lamentable deficiency; for example, from almost every part of the Empire there is a demand for trained geneticists, which is, and for the moment must remain, unsatis-For the solution of this problem we must look mainly to the universities of the Empire, and particularly of Great Britain. Again, what can be done to help the man now engaged in research? Is the time yet ripe for an extension of the principle already embodied in the highly successful Imperial Bureaux of Entomology and Mycology? For the establishment, for example, of Imperial bureaux of soil science, vetermary science, or agricultural economics? If so, on what plan should such new organisations be set up? Then there is the difficult problem of publications, and of the collection and interchange of information, so that a man examining an agricultural question on the Gold Coast, for example, may have at least a reasonable chance of starting with a knowledge of the work already done or being done in other parts of the Empire upon the same or connected problems.

The interchange of research workers is another matter to which a close analysis ought to be applied; if a definite and practicable scheme can be devised, there can be no doubt of its advantages. A man working alone or almost alone in a comparatively small tropical colony, far from the stimulus of companionship with his scientific fellows, must benefit enormously by a period of re-freshment (in the most literal sense of the word) at Cambridge, Rothamsted, or some similar centre; just as those who are fortunate enough normally to work in such centres may well obtain unexpected advantages from a complete if temporary change of surroundings, and the opportunity of applying the test of new conditions to hypotheses and results reached in laboratories and on land thousands of miles away. Another question of magnitude which can only be fully considered at a conference where the whole Empire is represented is the project of an Imperial chain of research stations-how many there ought to be, where situated, and how far each should endeavour to become the recognised authority for the whole Empire in one branch of agricultural science, besides meeting the imperative requirements of its own locality.

The conference must primarily apply itself to such administrative or semi-administrative questions; but naturally the groups of specialists present will discuss among themselves their own technical problems, which are scarcely suitable for the whole conference Possibly, however, the most valuable part of such a conference is not to be found in the official discussions of questions formally brought before the conference or committees of the conference; it is to be found in those private and unrestrained conversations in which one man of science really speaks to another with freedom about his own difficulties, hopes, methods, and The first Imperial Agricultural Research Conference is sure to be interesting, and it ought to produce most important results in the improvement of the machinery for the supply, equipment, and co-operation of men engaged in research. But one result should follow, which by itself will fully justify the conference; a mutual knowledge and personal appreciation between men scattered all over the British Empire, which will render their co-operation not only easier and more pleasant, but also more fruitful, than it can be made by any official machinery

#### Biometric Studies.

(1) The Biology of Population Growth. By Raymond Pearl. Pp. xiv + 260. (London: Williams and Norgate, Ltd., 1926.) 10s. 6d. net.

(2) Alcohol and Longevity. By Raymond Pearl. Pp xii+273. (New York and London. Alfred A. Knopf, 1926.) 15s. net.

THE present generation regards with relatively small alarm the probings of a paternal government into the life and death of the individual. Yet less than a hundred years ago the principle of laissez-faire was still dominant and the jurisdiction of Whitehall was strictly limited. No longer ago than 1753, a Bill introduced into the House of Commons to provide for a census of the people met with vehement opposition. One member "feared lest some public misfortune or an epidemical distemper should follow the numbering," while another was overpowered by the discovery that there could be "any set of men, or indeed any individual of the human species, so presumptuous and so abandoned as to make the proposal we have

just heard. I hold this project," he stated, "to be utterly subversive of the last remains of English liberty." Yet Great Britain did not lag behind other European States. The history of vital statistics is thus a short one, and, consequently, to glean further information of the populations of the past, we are compelled to resort to statistical assumptions based upon the very meagre data that exist

It is this ignorance of the course of population growth, of the variation in birth- and death-rates, over any but a very short period of time, and that limited mainly to a century of rapid industrial expansion, that makes the study of the 'laws of growth' so fascinating. Few workers have brought more originality to the study than Prof Raymond Pearl. Approaching the problem first from the mathematical viewpoint (in conjunction with Prof Lowell Reed), he concluded that a first approximation to the law was to be found in an equation of the form

$$y = d + \frac{k}{1 + e^{a_1 x + a_2 x^2 + a_3 x^3 + \cdots + a_n v^n}}$$

So long ago as 1838. Verhulst, a Belgian mathematician, had used this same curve, which he called the 'logistic curve,' as an expression of the law of population growth. This was unknown to Pearl and Reed when working on the problem, and they reached the result independently from biological reasoning. Eliminating mathematical symbols, Pearl states his 'law' as follows:

"Growth occurs in cycles. Within one and the same cycle, and in a spatially limited area or universe, growth in the first half of the cycle starts slowly but the absolute increment per unit of time *increases* steadily until the mid-point of the cycle is reached After that point the increment per unit of time becomes steadily smaller until the end of the cycle In a spatially limited universe the amount of increase which occurs in any particular unit of time, at any point of the single cycle of growth, is proportional to two things, namely: (a) the absolute size already attained at the beginning of the unit interval under consideration, and (b) the amount still unused or unexpended in the given universe (or area) of actual and potential resources for the support of growth."

Prof. Pearl shows that such a curve gives a good representation not only of the growth in body-weight of the rat and of the pumpkin, but also of the development of a population of yeast cells and populations of the fruit fly (Drosophila) kept under exact experimental conditions Applying the equation to human populations, it is found that the curve fits the recorded enumerations with extreme accuracy. Unfortunately, in all cases

the observed population-counts cover only a small part of the whole range of one cycle of growth In the United States and in England and Wales it is the earlier part of the cycle for which observations In France it is the late part of the cycle. What we require is a human population having census records covering an entire cycle of growth. This Pearl endeavours to supply by an analysis of the growth of the native population of Algeria, " the first and only example I have so far discovered of a human population virtually completing an entire single cycle of growth according to the logistic curve, and at the same time having definite census records covering practically the whole of the cycle" The 'fit' of the curve to the observed enumerations is again a good one. At the same time, we must not surrender ourselves entirely because of this 'goodness of fit' between the observed and the mathematically expected. Another curve of a flexible type may possibly fit the very limited observations equally well, but one has yet to be discovered based upon equally logical and justifiable reasoning

In adopting any 'law of population growth' it is essential to remember that it can be utilised for the estimation of past and future populations only over very short ranges of time. As Pearl points out, any alteration in the resources necessary for growth may entirely change the cycle along which a population is travelling. It was this change of resources that falsified (for the time being) the contentions of Malthus. He was unable to foresee the development of world-wide markets and the vast increase of food supplies, and thus the postponement of the pressure of population upon subsistence.

Pearl's experimental work is invariably stimulating, and his later chapters on density and population growth quicken one's interest. His data on normal sex behaviour cannot command the same respect. It is impossible to rid oneself of the conviction that no real assessment of the accuracy of the data is possible, and that a group of men aged from 50 to 75 years, even if of more than average intelligence, would not remember their average sexual activity per month in the different decades of life from puberty onwards Even if the data presented are substantially correct, the 'exposure to risk' incurred in all the social classes in this study is so great that one can scarcely credit the variation in sex habit as an important factor of the differential birth-rate

The same question confronts one in a lesser degree in reading Pearl's work on alcohol and the

duration of life. Can one ever obtain trustworthy knowledge of the drinking habits of the individual ? Pearl is satisfied that the information presented by him at least " is more accurate and comprehensive than any elsewhere available," and states that every critical safeguard of the accuracy of the records was adopted. He admits that it is by no means an easy matter to determine the precise effect of alcohol apart from other factors, and endeavours to eliminate the possible selective factor that determines whether a man is an abstainer or moderate drinker For this purpose he compares pairs of brothers, one an abstamer and the other a moderate drinker. The moderate drinkers, he finds, are slightly the better lives This is the same conclusion as that reached in the main study, that the moderate drinkers are as good lives as the abstainers, or even slightly better lives, while heavy drinkers are seriously penalised for their excesses as regards duration of life.

The study (and again more especially on its experimental side, of which a very detailed account is given) is full of interest and has been carried out with much care and labour. But it is not possible to feel satisfied that the selective factor has yet been proved to be non-existent, or that the last word has yet been said as to the effect of alcohol upon longevity—a dictum to which Prof. Pearl would be the first to subscribe A. B. Hill.

#### Religion in a Barbaric Kingdom.

Religion and Art in Ashanti. By Capt. R. S Rattray. With chapters by G. T. Bennett, Vernon Blake, H. Dudley Buxton, R. R. Marett, C G Seligman. Pp. xviii +414+116 plates. (Oxford: Clarendon Press; London · Oxford University Press, 1927.) 30s net.

THEN a magnificent feast is given and the numerous dishes are all excellent, it is perhaps ungracious to complain that the disorder of the courses makes digestion somewhat difficult, and that the table decorations (the appendices), though interesting in themselves, have not been arranged so as to decorate the table. Yet the excellence of his material provokes this complaint against the arrangement of Capt. Rattray's book. It is somewhat disconcerting to find the ideas of the soul, disease, and medicine all discussed under "funeral rites." So far as practical field method goes we would not change this at all; Capt. Rattray has derived all his knowledge from the sound method of watching ceremonies and discussing them with well-chosen informants, but it would have helped us to understand better had the ideas of the soul been given earlier, and not as an interruption to a ritual which had already begun. For an appreciation of Ashanti social, economic, and political organisation (as for most other 'socialled' savage societies) this knowledge of the spiritual background of life is essential, because religious ideas permeate everyday life and there is no trace of the division into civil and religious life that we are accustomed to in Europe. For example, law is founded on religious sanctions, just as the curious treatment of a new-born infant depends on the beliefs concerning the soul and the ever-powerful influence of the dead

It would seem that the one desire of the Ashanti is fertility, fertility of mankind and the fertility of the land, and for this end he must keep on good terms with the supernatural powers who are able to bless or blast the life source at every turn price, including human sacrifice, is too high to pay for the blessing, but for the Ashanti life is hard because of the multiplicity of supernatural powers. Capt. Rattray has defined these, not from any a priori conceptions of gods, demons or spirits. animism or mana, but from observation of ritual and the part the supernatural plays in the life of the individual. Thus there are the gods (abosom), including a High God in the sky, several gods, his children, all connected with water, an earth goddess, and possibly many others, the ancestral spirits (samanfo), and a vast class recognised by the Ashanti as suman, to which Capt Rattray reluctantly gives the name fetish. If he could, he would abolish that word entirely; instead, he has striven to correct the absurdly erroneous ideas of fetishism that have done so much to vitiate all works on West Africa. Some of the suman are extremely powerful, and it may be difficult for the observer to differentiate between their cult and those of gods, whereas other suman appear to be specially endowed amulets or talismans.

This, however, does not exhaust the catalogue of supernatural powers; there are forest spirits (fairies), monsters and witches, and animals and plants may have souls, which may influence the life of man. The description of a funeral service held over a dead elephant is very interesting, as the attitude here shown towards animals raises points in connexion with totemism. The usual socio-religious complex known as totemism does not exist in Ashanti, but there are certain animals and plants connected with the *ntoro* divisions (not clan divisions); lists of these *ntoro* animals and of animals possessing souls for whom funerals are

necessary are not identical, though there are a few species common to both Capt Rattray does not appear to have followed up this possible connexion, and it is quite probable that it would not lead to any conclusions, but it is a nice indication of the mental attitude towards animals which makes totemism possible.

The king of Ashantı does not appear to be a divine king; rather does the divinity of the authority rest in the king's stool or throne Much insight into the Ashanti religion and its relation to the kingship may be gained from the description of the Odwira ceremony, previously known as the Yam custom, and famous for the amount of intoxicating liquor drunk and of human blood These two features, though so horribly prominent to the first European observers, are merely incidents to the Ashanti in what was really an annual purification ceremony for the king and the whole nation before the new harvest might be The king honours the ancestral spirits, and the chiefs and people pay allegiance to the king The gods, ghosts, and other spirits must eat, then the king, his chiefs, and people may do so ceremony, which lasted many days, must have been of great political and economic value to the kingdom It seems a pity, however, to call it a "rite de passage," a title which so aptly classifies those ceremonies connected with transition periods in the life of the individual which mark the various phases of personal development, although M. Van Gennep himself, who coined the phrase, did include certain seasonal festivals under this heading.

The cult of the dead kings of the Ashanti suggests interesting politico-economic questions, for in addition to the extremely complicated beliefs concerning the soul, or rather the various souls that go to the spirit world (in the case of the king accompanied by widows and other attendants who are killed for that purpose), there is also a cult of the royal skeletons, to each of whom is appointed a living wife. Moreover, vast treasury in gold was owned by the dead kings and guarded by a standing army of about one thousand men This moneyfor gold dust has its standard weights and values in Ashanti-could be 'borrowed' by the reigning king for ceremonies or national emergencies. The fact that the king must borrow and not merely take the royal treasure may have given stability to the government and added to the credit of the country.

It is to be hoped that Capt Rattray may still be able to obtain further information concerning this

primitive gold reserve. Was tribute paid to the dead and not to the living monarch, or was it divided between them? In what manner did the king make repayments to the coffers of the dead, and at what periods? Were the natural sources of gold controlled in any way, or might any man wash for alluvial gold? Numerous examples are given of fines which must be paid in expiation for breaking taboos or in the more ordinary course of justice, but it is not always clear if these were due to the king, clan chief, gods, or as compensation to the injured party One notable example of direct taxation, however, is that half the bride-price of daughters of the royal house, as well as of granddaughters and great-granddaughters of chiefs, passes to the king

Apart from the practical functioning of the gold reserve, there is an interesting question regarding its underlying purpose and possible origin, on which it may still be possible to throw light Capt Rattray has told us that when a commoner is buried, his wife provides some gold dust, or a small nugget, which is tied in the loin-cloth of the deceased. It is called kra sika, 'soul's money,' and is intended for the purchase of necessaries in the world of ghosts. Is it possible that the treasury of the kings originally served the same purpose, or that even quite recently, while fulfilling an entirely different function, the same belief was held with regard to it? It is to be hoped that in the forthcoming volume which Capt. Rattray promises us, he may be able to tell us still more about the economic side of this highly organised barbaric kingdom. All who have enjoyed Capt. Rattray's first work on Ashanti will appreciate this, his second volume, and will look forward eagerly to the publication of the third.

Brenda Z. Seligman.

#### Chinese Ornithology.

Bulletin of the Peking Society of Natural History.

Technical Series, No. 1. A Tentative List of
Chinese Birds. Part 1 · From Colymbiformes
through Coractiformes. Compiled by N. Gist Gee,
Lacy I. Moffett, and G. D Wilder. Pp. viii
+144. (Peking: Peking Society of Natural
History, 1926.) n.p.

IN Great Britain it seems as if almost every nature-lover who can wield a pen writes, or tries to write, a work on British birds. In China the reverse is the case, and since 1877, when David and Oustalet brought out their "Birds of China," no one has attempted to compile another such

publication Latouche is now engaged on "Birds of Eastern China," and both he and Lord Rothschild have written several valuable articles in the Ibis on the birds of Yunnan, whilst desultory articles on the avifauna of other portions of the great Chinese Empire have appeared from time to time in the same and in other journals. Messrs N Gist Gee and his collaborators are now bringing out a tentative list of the birds of the whole Chinese Empire, and we congratulate them very heartily on this part, the first, which has appeared in the Bulletin of the Peking Society of Natural History The work is one which is very badly wanted, for however good David and Oustalet's work was when written, it is now long out-of-date, and a vast amount of ornithological work has been done since that time. The tentative list will, as its name implies, include all those birds which occur in the eighteen provinces of China, its islands, and in eastern Mongolia, east to Sakhalin.

The classification adopted is that of Knowlton in his "Birds of the World," and the nomenclature is taken from Hartert, "Die Vogel Palaarctischen," and other modern authors No suggestion is made that the list is in any way complete but, such as it is, it is published as a working basis for further study and, in this respect, it is almost impossible to over-estimate its value to both present and future workers The list contains the scientific, English and, wherever possible, the Chinese name of each bird, after which its distribution is given. The author of each scientific name is given, but no reference is made either to the first description or to later synonymy, an omission to be regretted. though the inclusion of these details would doubtless have at once overburdened the work and rendered it impossible to carry out.

It is out of place in reviewing a work of this nature to criticise minor details, and it may suffice to say here that as a whole the compilation appears to be excellent and thorough, and the fact that mistakes in nomenclatures and a few inaccuracies in geographical ranges naturally find their way into its pages will not in any way affect its immense usefulness and its great influence in furthering the cause of Chinese ornithology. It is a praiseworthy and very ambitious attempt to fill a greatly felt want, and one which we hope will probably inaugurate another cycle of ornithological research in China. The present volume contains the Colymbiformes, storks, herons, ducks, Accipitres, game birds, rails, waders, gulls, pigeons, and scansorial birds, leaving the great order of Passeres still to be dealt with.

- (4) Necturus: a Laboratory Manual. By L A Adams. Pp. vm + 72 (New York: The Macmillan Co., 1926.) 4s. 6d.
- (5) Anatomy of the Wood Rat Comparative Anatomy of the Subgenera of the American Wood Rat (Genus Neotoma) By A. Brazier Howell. (Monographs of the American Society of Mammalogists, No. 1.) Pp. x + 225 + 3 plates (Baltimore, Md · Williams and Wilkins Co., London Baillière, Tindall and Cox, 1926.) 228 6d. net
- (6) An Atlas of Human Anatomy: for Students and Physicians. By Dr. Carl Toldt, assisted by Prof. Alois Dalla Rosa. Adapted to English and American and International Terminology by Dr. M. Eden Paul. Revised edition in 2 vol. Vol. 1 First section, A. The Regions of the Human Body, B Osteology; Second section, C: Arthrology, Third section, D: Myology. Vol 2. Fourth section, E: Pp. iv +400Splanchnology, Fifth section, F. Angeology, Sixth section, G: Neurology; H The Organs of the Senses. Pp. ii + 401-985. (New York. The Macmillan Co., 1926.) 42s. net
- (1) THE German translation of a treatise on comparative anatomy by four Dutch zoologists is a welcome summary of the present state of vertebrate anatomy, which deals with vertebrates in the same way as, but more fully than, Gegenbaur and Bütschli have dealt with the animal kingdom as a whole. Some of the illustrations are borrowed from Bütschli's text-book, the merits of which have already been described in NATURE; and the rest of the 987 figures are drawn in the same clear semi-diagrammatic way. The volume is probably the best text-book of comparative anatomy. The chapter on the skeleton (by Prof. Versluys, of Vienna), dealing as it does not only with recent but also with fossil vertebrates,

is worthy of special note for its excellence and comprehensiveness

- (2) The fact that Hyman's "Elementary Zoology" is the second edition of a practical manual of which seven impressions have been sold in six years leaves no doubt as to its usefulness in the University of Chicago. It deals in a comprehensive way with the technique of the practical examination of the anatomy, embryology, and cytology of a large series of invertebrates and vertebrates. It has no illustrations
- (3) and (4) The guides to the dissection of the dogfish and Necturus are simple, clearly written dissecting manuals for elementary class work. They are both well done, but have no illustrations.
- (5) Howell's work on the wood rat is an original memoir on the anatomy of a common American mammal The author points out that while there are excellent accounts of the anatomy of such spectacular curiosities as the aye-aye and the marsupial mole, we are woefully ignorant of many of the common mammals His book is one of a series that is being issued by the American Society of Mammalogists to make good this defect work provokes comparison with the investigations of the tree shrew and the tarsier respectively by Profs. Le Gros Clark and Woollard, recently published by the Zoological Society of London, and such a comparison reveals the curious fact that the American author has wholly neglected the central nervous system, to which the British anatomists devote particular attention
- (6) Toldt's well-known atlas of topographical anatomy is perhaps the most comprehensive of the many atlases now available for students, and as such is well worth making accessible in this second edition for English-speaking readers. While most of the illustrations are excellent, a few of the wood blocks seem to be worn out so that the detail is lost in the impressions made from them. Dr. Eden Paul's contribution to the volume is not altogether relevant: his reliance upon Macalister's text-book, which was an excellent guide more than thirty years ago, is not an adequate basis for the explanation of a modern atlas.

#### The Chemistry of Wood.

The Chemistry of Cellulose and Wood. By Dr. A. W. Schorger. (International Chemical Series) Pp. xiv+596. (New York. McGraw-Hill Book Co., Inc; London: McGraw-Hill Publishing Co, Ltd., 1926.) 30s. net.

IN organic chemical industry there are many signs of wider and increasing activity. Synthetic alcohols are leading to new supplies of solvents and

other products, and in addition the possibilities of wood as a chemical raw material are being realised Within the last decade artificial silk from wood has become abundant and cheap, and is now being used to an extent never approached by the limited and costly natural silk The saccharification of wood and cellulose has recently become prominent as a possible cheap source of power alcohol, acetone, glycerine, and other products of fermentation, and although not without technical difficulties, promises to open the way to new industries In addition to these prospects there is every likelihood that wood cellulose will be pressed into use as a substitute for the more costly cotton cellulose in many existing industries such as film, celluloid, explosives and enamels

Wood, unlike coal and oil, requires only land and the sun for its continuous supply. Fortunately, reafforestation is receiving active attention in Great Britain, as in the main timber-producing countries, and there is no doubt that many requirements can be assured with practically small land reservations. The chemistry of wood and wood cellulose is consequently of increasing importance. Considerable attention appears to have been directed to the subject by the study of wood as a source of explosives during the War

Wood and its products are, however, complex and varied, and a systematic conception of their chemical and physico-chemical behaviour has been wanting. Dr. Schorger, Director of Chemical Research, C. F. Burgess Laboratories, has carried through successfully the difficult task of collecting the scientific data available on the chemistry of wood in a concise account, necessarily including some mention of cotton cellulose and its modified forms. It is made clear in the preface that the technical side of the subject is not the main theme, but the research student and worker will find the literature effectively summarised, while new prospects of research are to be found on almost every page of the book.

Broadly, the subject matter covers wood and the reactions of wood, lignin, hemicelluloses, gelatinised cellulose, oxy- and hydrocelluloses, the saccharification, distillation, and digestion of wood and wood celluloses, and analytical methods, concluding with a useful author and subject index. The many problems of chemical constitution, together with modern views on gelatinisation and other physical phenomena, are fully considered, while manufacturing processes concerned with wood and wood cellulose are adequately, although more generally, described.

In such a summary it is inevitable that occasional erroneous results can be found and additions suggested Thus, Jentgen's statement that dry cellulose will take up 3 per cent. of moisture from all known drying agents is obviously incorrect and should be omitted. The following corrections might also be made. on p 536 amiline hydrochloride to aniline acetete, on p 578, under copper number, 451 to 541, and on p 184, Irvine's formula for cellulose is incorrectly reproduced. The paper, printing, and binding are excellent, and the work is to be recommended as the most satisfactory survey of the subject in a convenient handbook form

A FORSTER

#### Our Bookshelf.

Department of Scientific and Industrial Research The Cleaning and Restoration of Museum Ex-Third Report upon Investigations conducted at the British Museum. Pp. v+70+58 (London. H M Stationery Office, 1926.) plates 5s. net.

CURATORS of museums as well as private collectors not infrequently find some or other of their charges incapable of resisting, unaided, the ravages of time in their many forms. In this volume, which amplifies two previous reports, Dr. A. Scott describes his experiences in the cleaning, restoration, and subsequent preservation of various exhibits from the British Museum and of some other well-known objets d'art. Sections of the book are devoted to prints and pictures, to stone and earthenware, to objects of silver, iron, lead, copper, bronze and wood, and to textiles; there are also described and illustrated some interesting 'fakes,' founded on a genuine basis and so cleverly executed as to deceive even experts until some abnormal feature of decay suggested the necessity for detailed scientific examination. The text concludes with some notes of a general character, dealing with apparatus, utensils, and media likely to be of value for specific purposes.

While the cleaning and restoring processes should preferably be left to skilled hands, the amateur, by adherence to the methods laid down, should be able to achieve satisfactory results. The timely admonition against the use of preparations of unknown composition is one which may well be extended to spheres other than that with which

we are now concerned.

The efficacy of the methods adopted is illustrated by a number of well-produced, interleaved plates showing in many cases the various subjects before and after treatment, and on occasion some other point of particular interest.

Here, then, is a book almost unique of its kind and invaluable to those for whom it is primarily intended; further, it should serve, in these days of the revival of 'general knowledge,' to stimulate the interest of a larger sphere of readers in a number of cognate subjects.

Handbook of Non-Ferrous Metallurgy Prepared by a Statf of Specialists Donald M Liddell, Editor-in-Chief In 2 vols Vol 1 Pp x1+692 Vol. 2 Pp v+693-1440 (New York. McGraw-Hill Book Co., Inc., London McGraw-Hill Publishing Co , Ltd , 1926 ) 60s net

There are many encyclopædic text-books of metallurgy, and a new one must justify itself by fullness and accuracy of treatment The present volumes are the work of a large number of contributors, and there is no attempt to give a critical Instead, there is a series of survey of the subject monographs on the metals, most space being given to those which are of the greatest industrial im-Each monograph is by a specialist, so that the information may be supposed to be abreast of modern practice This appears to be true of the common metals, and such important processes as the electrolytic extraction of zine are treated in detail. The term metallurgy has been interpreted by most of the writers as referring mainly to the extraction of the metals, and only in a few instances is there more than a brief outline of mechanical or thermal treatment or of the preparation of alloys. Such general processes as crushing, ore concentration, roasting, sintering, and electric smelting are considered in separate articles as well as meidentally under the heads of the several metals extensive and useful section deals with the materials of metallurgical construction Metallography only receives limited attention, and the brief article on the subject is mainly confined to phase-rule questions, but a few of the authors give some account of the metallography of their special section. Throughout the greater part of the book theory is subordinated to practice, and it is mainly as a guide to current ore-dressing and smelting practice that it will be found useful. The least satisfactory section is that which deals with the rarer metals, in which there is now a great metallurgical interest.

The Geography of Witchcraft. By Montague Summers (The History of Civilisation Series.) By Montague Pp xi+623+8 plates. (London. Kegan Paul and Co, Ltd.; New York. Alfred A. Knopf, 1927.) 21s net.

"THE Geography of Witchcraft," the title by which Mr Summers distinguishes the second of his studies of witchcraft in this series, is something of a misnomer. Except that his chapters have geographical headings, his treatment is purely historical Further, he deals only with Greece and Rome, England, Scotland, New England, France, Germany, Italy, and Spain An adequate geographical study of witchcraft should surely go farther Even within the boundaries of Europe he has omitted areas which are of first-rate importance in any investigations of the distribution of the belief and of special significance in relation to the question of origins. In Scotland, for example, where Mr. Summers notes that even the fairies have a sinister character, there seems to be a convergence of two lines of development, one coming from the north of Europe and the other from the south.

The explanation of the restriction which the author has imposed upon himself no doubt is to be tound in the fact that his interest lies in the theological side of his subject. He has therefore confined his attention to those countries in which the witch is to be regarded as a subject under the ban of the Church and a heretic, rather than as a survival from an earlier stage of culture. In this volume, as in the preceding, due allowance must be made for the author's strong theological bias, but so far as the facts are concerned, his account for each of the countries with which he deals is comprehensive, detailed, and accurate to a degree beyond that attained by any other book on the subject

A Botanist in the Amazon Valley. an Account of the Flora and Fauna in the Land of Floods. By Prof R Ruggles Gates Pp 203+11 plates (London H. F. and G Witherby, 1927) 7s 6d net

The opportunity of a voyage up the river Amazon so far as Teffé, which, including stays of a few days at Para, Manaos, and Teffé, occupied about six weeks, has led Prof. Gates to give an account of the general scenery and vegetation which can be seen from the deck of steamers and from his brief visits To any one making the journey by to terra firma one of the Booth line boats and river steamers, this narrative by a botanist will be of interest, but for the serious student Prof Gates adds very little to our knowledge, and he himself is undoubtedly the chief gainer by this very interesting opportunity, of which he appears to have taken full advantage, judging from his frequent allusion to his impedimenta for collecting, etc The book appears to be the author's diary in print, so that much similar information is repeated, but a good many items will be of value to others who may make the journey. We are surprised that Prof. Gates compares the

We are surprised that Prof. Gates compares the huge leaves of the *Victoria Regia* with their vertically upturned edges to dinner plates; nor is he correct as to the colour of the flowers, since they are pure white at first and turn pink in the course of the day and then dull crimson as they fade. Two short chapters at the end of the book on palms and other trees of the Amazon, and on woods and timbers of this region, are of value.

Sternhaufen: ihr Bau, ihre Stellung zum Sternsystem und ihre Bedeutung für die Kosmogonie. Von P. ten Bruggencate. (Naturwissenschaftliche Monographien und Lehrbucher, Herausgegeben von der Schriftleitung der Naturwissenschaften, Band 7) Pp v + 158 + 4 Tafeln (Berlin: Julius Springer, 1927) 15 gold marks This is a very comprehensive monograph dealing with star-clusters and the work of various investigators on the problems of their distribution in space and of their structure. In Part 1 the author gives the general distribution of the clusters in the sky and describes the methods employed by Charlier, Kapteyn-Schouten, and Shapley for determining their distances. Parts 2 and 3 are devoted to investigations on the arrangement of the component stars of the clusters and the

dynamical problems involved. The work of Eddington, Jeans, Shapley, and Von Zeipel naturally forms the framework of the chapters included. In Part 4 the author considers the question of star-clusters in relation to a general scheme of cosmogony. As this monograph is intended essentially for students, references to original papers are given in footnotes. In the list of catalogues of star-clusters, reference should have been made to that compiled by Melotte from the Franklin Adams Chart, and published as Memoirs of the Royal Astronomical Society, vol. 60

Through Kamchatka by Dog-Sled and Skis: a Vivid Description of Adventurous Journeys amongst the Interesting and Almost Unknown Peoples of the most inaccessible Parts of this remote Siberian Peninsula. By Dr. Sten Bergman Translated from the Swedish by Frederic Whyte Pp 284+16 plates. (London: Seeley, Service and Co, Ltd, 1927) 21s net.

In this book Dr Bergman describes several journeys which he and his wife took a few years ago in the interior of Kamchatka, when he was leader of a biological and ethnographical expedition sent by the Swedish Geographical Society is the best kind of travel book, with no tedious details of daily routine, but enough incidents of travel to illustrate the customs and habits of the people and the difficulties of the road. There is also much original matter in the account of visits paid to the Lamuts and Korvaks in the remoter parts of the peninsula, and to the degenerate and disappearing Kamchadals. The book is useful as giving a full and readable account of a part of Asia which is little known and seldom visited except by trappers and fur dealers. The maps and illustrations add to its value Fuller accounts of the results of the expedition are now being published in Swedish scientific journals.

Delineations of American Scenery and Character. By John James Audubon With an Introduction by Prof. Francis Hobart Herrick Pp. xliv+349. (London: Simpkin, Marshall and Co, Ltd, 1926.) 18s. net.

Audubon's "Ornithological Biography," as he called the text in five volumes which accompanied his great work on "The Birds of America," contained a number of descriptive articles of a general value. Fifty-nine of these essays and two of his prefaces are reprinted in this volume, to which his biographer adds a short introduction Most of the essays are sketches of pioneer life in the Ohio and Mississippi valleys, Labrador, Newfoundland, and New England between 1808 and 1834 A few treat more particularly of animal life. They were all written in the places and among the scenes they describe and portray vividly many aspects of life in America that have now passed, submerged in the flowing tide of population. Thus they fulfil the writer's aim, which was to record America as he saw it before man effected drastic changes on the face of the country. The volume is a useful contribution to American natural history and geography.

# The Actinium Series and the Order of Stability of Radioactive Isotopes.

One of the outstanding problems of radioactivity is the exact relation of the actinium to the thorium and uranium-radium disintegration series. That the actinium series starts at uranium I or an isotope of uranium, includes uranium-Y and ends at an isotope of lead after five a-particles have been expelled between protoactinium and the end product is regarded as proved by the experimental evidence But the atomic weights of members of the series are not known, protoactinium is the only member of the series whose atomic weight might be determined by the usual methods, but this constant is still lacking owing to the very great difficulty of making a complete separation of protoactinium from its homologue tantalum An investigation with the mass-spectrograph of uranium or of uranium-lead, leading to the discovery of isotopes not ascribable to the uranium-radium series, might also throw light on the atomic weights of members of the actinium series. This has yet to be made.

Failing experimental evidence, it may be asked if any useful purpose is served by attempts to predict what these atomic weights may be. As they lead not only to new values of these atomic weights but also to a generalisation with respect to the stability of radioactive isotopes which in part is applicable to isotopes of mactive elements, as I hope to show they do, I think they are justified.

I assume (a) that the actinium series starts from an isotope of uranium, ends at an isotope of lead, and includes the product uranium-  $\Gamma$ , for all of which the experimental evidence is very strong; (b) that if an element of even atomic number has isotopes of odd atomic mass, these are likely to be one and three units less than the mass of its most stable isotope; (c) that the most stable mass of an element of odd atomic number is likely to be one unit greater than that of the most stable mass (of even number) of the element next below it. (In (b) and (c) I am merely applying to elements in the range of atomic numbers 82-92 what is obvious from  $\Gamma$ . W. Aston's results on elements in the range 34-80)

Now the most stable isotopes of elements 92, 90, 88, 82, and 80 are known to have masses 238, 232, 226, 208, and 202 respectively. Therefore according to (c) the most stable isotopes of elements 93, 91, 89, 83, and 81 are likely to have masses of 239, 233, 227, 209, and 203 respectively. (This is certain for element 83 and very probable for element 81.) Can protoactinium have the atomic mass 233 assigned to the principal isotope of element 91 ? Now, so far as has been investigated, the most stable isotopes of elements 92, 90, 88, 8 $\check{6}$ , 84, 83, 82, and 81 are either 'a-rayers' of long life or products which may be described as potentially 'a-rayers' (bismuth 209 being regarded as the parent of thallium's isotope 205, lead's isotope 208, the parent of mercury's isotope 204, etc.). Proto-actinium, an ' $\alpha$ -rayer' with an estimated period of 10,000 years, is clearly in this class; actinium, a ' $\beta$ -rayer' with a period of 20 years, is clearly not. The former may therefore have an atomic mass of 233, the latter may not have an atomic mass of 227; and these two statements are consistent with one another,

since the former element is the paient of the latter by an a-particle change.

An alternative value for the atomic mass of protoactinium would be 235, since, as F. W. Aston's results. show, an element of odd atomic number may have a second isotope two units greater m mass than that of the principal isotope. The value 233, however, leads to a value of 237 for the mass of that uranium isotope which is the head of the actinium series, a value consistent with assumption (b), whereas the value 235 leads to a value 239, which is not. Again, as the mass 227 may not be assigned to actimum, the mass 231 may not be assigned to protoactinium If, therefore, the atomic mass of protoactinium is an odd number, that mass must be 233 if the assumptions I am making are valid. This value fixes the atomic weights of the remaining members of the series unless it can be shown that a further a-particle which has been overlooked, or a massive particle other than an α-particle, is expelled by some member of the series

Formerly I regarded the actinium series as beginning on a uranium isotope of mass 239 or 235 and ending at a lead isotope of mass 207. This view was suggested by the fact that the transformations ionium to radium-B, radiothorium to thorium-B, and radioactinium to actinium-B, are all similar as regards the radiations expelled, and in that each product in these transformations has a period on the average 800 times smaller than that of its parent, and yet the average rate of decay of products of the first transformation is  $7.5 \times 10^3$  times that of the corresponding products of the second and that of the second about 40 times that of the corresponding products of the third.

I argued that as the factor  $7.5-10^3$  corresponds to a difference in mass of the isotopes of 2, then its square root (of the same order as 40) corresponds to a difference in mass of 1. I concluded, therefore, that if x, x = 2, x - 4 represent atomic masses, and the first and second those of, say, ionium and radiothorium respectively, the atomic mass of radioactinium would be not x - 4 but x - 3.

This implies, I see now, that the decreasing order of stability of the masses is x, x-2, x-3, x-1. But if this order were x, x-2, x-1, x-4, as I hope to show it is, then the proper conclusion from this relation between the periods is that the atomic mass of the actinium product is x-1, not x-3. The mass of radioactinium should be therefore 229, not 227, and, in consequence, that of every actinium product should be 2 units higher than I formerly thought.

If protoactmum has an atomic mass of 233 the masses of actinium products of elements 92, 91, 90, 89, and 88 are known, and their stabilities may be compared with the corresponding products of the radium and thorium series. Two empirical relations appear to connect stability, as measured by half-value period, with mass.

I. For an element of even atomic number the masses of its  $\alpha$ -ray and of its  $\beta$ -ray isotopes are in decreasing order of stability when arranged in the orders x, x-2, x-1, x-4, x-3, etc., respectively, x being an even number and the

atomic mass of the stablest isotope

II For an element of odd atomic number the masses are in decreasing order of stability when arranged in the same order as the  $\beta$ -ray isotopes of an element of even atomic number, x the atomic mass of the principal isotope is, however, an odd number. (For all radioactive elements the isotope of mass x is an 'a-rayer'; for a comparison of its stability with that of its  $\beta$ -ray isotopes, however, it may be conventionally regarded as a ' $\beta$ -rayer' of very long period and therefore of very great stability.)

For element 92 the decreasing order of stability is uranium I (238), actinouranium (237), uranium II (234), by rule I it is 238, 236, 237, 234, 235. For element 91 the same order is protoactinium (233), uranium-Z (234), uranium- $X_2$  (234); by rule II. it is 233, 235, 234, 237, 236. For element 90 the order is thorium (232), ionium (230), radiothorium (228), radioactinium (229) for 'a-rayers'; by rule I. it is 232, 230, 231, 228, 229, for ' $\beta$ -rayers' the order is thorium (232), uranium- $X_1$  (234), uranium-Y (233); by rule I. it is 232, 234, 233, 236. For element 89 the order is stablest isotope (227), actinium (229), mesothorium-2 (228), by rule II. it is 227, 229, 228, 231. For these four atomic numbers, then, the rules give values consistent with the known or assigned values of all the known isotopes.

A more general torm of these rules holds for the isotopes of several of the mactive elements investigated by F. W. Aston. Granted that an element of even atomic number has one or more isotopes of odd mass number, then it is to be expected that (a) the even mass numbers may be arranged in order of decreasing stability in two series. one, in which the mass numbers increase uniformly from the mass number of the principal isotope, and the other in which the mass numbers decrease, (b) any odd mass number (capable of existing) when arranged with the even mass numbers in decreasing order of stability, follows the mass number one unit greater in an 'increasing series and the mass number one unit less in a 'decreasing' series. For example, the experimental decreasing order of prevalence in Nature (here regarded as the criterion of stability) of the isotopes of selenium is 80, 78, 76, 82, 77, 74. The 'increasing' series is 80, 82, the 'decreasing' 80, 78, 76, 74, and the odd mass number follows 76, as it should according to the general form of the rule

Again, the experimental order for the isotopes of xenon is 129, 132, 131, 134, 136, 128, 130, which is nearly consistent with the orders given by the rule. 129, 132, 131, 134, 136, and 132, 130, 128. Of the elements investigated by F. W. Aston the experimental order of decreasing stabilities of isotopes is consistent with those given by the rule for sulphur, selenium, krypton, neodymium, and lead, is nearly consistent for xenon, cadmium, and mercury, and is meconsistent for tin and the light elements magnesium and silicon.

In element 84, despite the fact that polonium has the longest period, the order of decreasing stability of the remaining isotopes is radium-A (218), thorium-A (216), actinium-A, radium-C' (214), and thorium-C' (212) By rule I. the atomic mass of actinium-A should, therefore, be 217, and this leads to a value for the atomic mass of 209 for the end-product.

In element 83 the stabilities of the three C-products may be compared first as ' $\alpha$ -rayers' and secondly as ' $\beta$ -rayers' According to the rules, in the former case an atomic mass of 213 or 211 is suggested for actinium-C; in the latter case a mass of 213. These values lead to values of 209 and 207 respectively for the atomic mass of the end-product.

In element 82 rule Î. fixes the atomic mass of actinium-B as 211; for a mass of 213 the half-value period of actinium-B should be less instead of, as it is, slightly greater than that of radium-B; the value 211 leads to a value of the atomic mass of the end-product of 207.

Finally, in element 81 rule II. gives possible values of 209 and 207 to the atomic mass of actinium-C", which lead to values of 209 and 207 respectively for the atomic mass of the end-product. On the whole, the application of the rules to these four elements, though not satisfactory, points to a value of the atomic

mass of the end-product of the actinium series of 209 rather than 207. This is, of course, the value to be expected if protoactinium has an atomic mass of 233, and if there is no abnormal particle expelled by actinium-X or other member of the series.

A S. Russell.

## On Incomplete Spawning and the Problem of Fertilisation in *O. edulis*.

DURING recent investigations on the relation of spawning in the native oyster (O edulis) to external conditions, certain phenomena, which it is advisable to record early, have recently been observed

At the end of the new moon tides at the end of July and in the beginning of August (1927), there was a fair to heavy general spawning of oysters (O. cdulis) on the beds in the upper part of the Fal In this general spawning it was observed that a large proportion of the spawning individuals had (apparently) tailed to fertilise a large proportion of their eggs, varying in individuals from 20 per cent. to 60 per cent, with occasionally a higher proportion. The successfully fertilised eggs were found in the condition of development of 1, 2, or 3 days old embryos, while the unsegmented eggs showed at the same time great variation in size, and in many cases, but in small proportion, a variable number of nuclei to as high a number as 13 Unsegmented eggs contaming many nuclei may be associated with either polyspermy, or with conditions which prevent segmentation after fertilisation, or may possibly also occur as a result of degenerative changes in the unfertilised egg.

It is a fact, however, that there has been a large wastage of oyster eggs on the Fal Estuary oyster beds at the critical spawning time in early August.

At the same time as it was found that a high percentage of eggs remained unsegmented, due apparently to not being fertilised, it was noticed that the percentage of incompletely spent female individuals had increased from an average of about 10 per cent to 17 per cent. (in comparable samples each amounting to 700 individuals), so that eggs in considerable quantities have also been lost from an inefficient response to the spawning stimulus

The incomplete spawning of female oysters has previously been shown to be not uncommon (Jour. M.B.4., vol. 14, p. 974, 1927), and elsewhere (Fish. Invest., London, vol. 6, 3 and 4; 1924) that unspent ova may either remain in the gonad to produce a 'curdled fish,' and become absorbed later, or be excreted in masses on to the shell and covered with a calcareous deposit to form what Mr. Haynes, I believe, was the first to describe as an 'excretion blister.' The large proportion of incompletely spawned females recently found among the Fal Estuary oysters is nevertheless unusual, as is illustrated by the occurrence of only 2 to 6 per cent. incompletely spent individuals in more than 7 comparable samples of 100 oysters examined at the same time from West Mersea, Essex. In one sample of 100 individuals from Thornfleet, West Mersea, however—and currously on Aug. 2-there was the unusually high percentage for 1927 of 12 incompletely spawned. (These percentages are accumulative from the beginning of the spawning season)

The incomplete natural spawning of female oysters can probably be explained satisfactorily as a result of normal natural causes, and is probably always relatively high in the Fal Estuary. It seems highly probable that the phenomenon is due to the occur-

rence of temperature fluctuations at about the spawning period. Thus, this year it was found that the temperature over the Upper Fal oyster beds fluctuates to an unexpected extent with the neap and spring tides; for example, on July 27 temperatures over the beds generally ranged from 62° to about 63° F., the temperature being about 62° at 8½ fathoms at about low water above Turnaware Bar. Aug 3 at the same station at the same depth at half ebb-tide the temperature was below 60° and less that 59° at 14 fathoms at the lower end of the oyster beds. A similar fluctuation was observed in the succeeding neaps and springs, and on Aug. 17 the remarkably low temperature of 57° was recorded m 14 fathoms at the lower end of the beds, with a corresponding reduction in temperature over the whole of the beds It is clear, therefore, that at the spring tides relatively cold water sweeps directly into the Fal Estuary and over some parts of the oyster beds from the deeper parts of the English Channel, while during the neap tides the tidal oscillation of water is reduced and in summer weather the water becomes relatively warm. It is not possible, however, to discuss these matters and their bearing on spawning fully here.

In samples of oysters from the Fal Estuary, examined from one week to a fortnight after the abnormal spawnings were observed, individuals were found carrying normal shelled larvæ and at the same time a small proportion of much smaller and frequently abnormal shelled larvæ, the latter no doubt being the product of the fertilisation of scarcely ripe eggs; as the abnormal larvæ will probably not live, there will be additional loss of some of the eggs which were

fertilised.

It would seem, therefore, that at the period of the new moon tides at the end of July in 1927 on the Fal Estuary oyster beds, there was a powerful stimulus exerted on oysters to spawn, and that a large proportion of those female oysters, which were approaching maturity, spawned either incompletely or apparently before collecting sufficient sperm to fertilise their eggs Since normally segmenting embryos occurred alongside unsegmented eggs in the mantle cavity of the same individual, it is not necessary to infer that abnormal substances in the seawater have interfered with and affected the process of fertilisation. On the other hand, the occurrence of large numbers of unsegmenting eggs in a high proportion of the spawning oysters on beds which are depleted in numbers necessarily raises the question as to whether enough male-functioning oysters exist in the locality to supply the relatively widely scattered It is possible that not enough sperm had been emitted by the oyster population to enable those females ripening at the end of July and in early August to collect a sufficiency to fertilise their eggs. The lack of sperm may be due either to a shortage of males or to an incorrect timing of the spawning of the males in relation to the maturing of the females.

There is, however, no means of testing these views in this or a similar occurrence until further researches show at least how and when the native oyster stores the sperm destined to fertilise its ova. Hoek, the great Dutch naturalist, found and figured in 1883 (Tyd. Ned. Dierk. Ver, Supp. Deel 1, Leyden) discrete sperm in the renal tubules adjoining the external genital aperture in a female oyster, but the precise situation of this functional spermatheca has not yet been defined, nor has the condition of this region been determined in a significant number of ripening females to establish the facts of the normal method of fertilisation in O. edulis. A spermatheca which should contain enough sperm to fertilise any number of eggs from half a million to a million or more, in

oysters of 5 years of age or more, ought not to be difficult to demonstrate

An additional point of interest arising out of the observations recorded above is that owing to the large number of oysters which have spawned incompletely, it is probable that there will be a slightly increased mortality, and also an unusual number of shells with excretion blisters in the form of subspherical calcareous projection containing rejected ova, as some newly formed ones have already been seen From data which are being accumulated, evidence is being obtained that the incomplete spawning of females is a not uncommon cause of death, which will need to be considered carefully, in relation to occurrences of unusual mortality among ovsters. especially when such occurs in seasons of abnormal weather J H. ORTON

Marine Biological Laboratory, Plymouth, Aug 21.

#### Published Values of the Velocity of Light.

Some time ago, requiring a list of the determinations of the velocity of light made by different investigators, I, not unnaturally, referred to tables of this constant, some of those which were available to me being given by authorities of such ligh standing that their trustworthiness was, to my innocent mind, absolutely out of question

As a result, I found myself led astray to such an extent (amounting to the withdrawal, at the eleventh hour, of a paper already set up in type and about to appear in a well-known scientific publication) that I feel it incumbent upon me to ask the hospitality of the columns of NATURE to reveal the almost meredible confusion existing in most works of reference dealing with this particular question, as a warning to the unwary about to put their trust in second-hand information, instead of referring to the original papers themselves, and at the same time to put a plea before those on high who, being busy (and human, despite their exalted state), are inclined to quote from memory, initiating thereby errors which are copied and recopied indefinitely, until they mislead the investigators themselves who have made the experiments of which they so lightly misquote the results!

The discovery took place when I noticed extraordinary discrepancies between a table of the values of the velocity of light, given by Prot. A. A. Michelson in the Journal of the Franklin Institute for Nov. 1924, and reproduced in Nature for Dec 6, 1924 (p. 831), and Table 166 of the "Recuell de constantes physiques," by Abraham and Sacerdote, an imposing volume of 753 pages in 4to, published under the auspices of the Société Française de Physique. I beg leave to reproduce here the relevant portions of these two tables (for convenience's sake I have given a number to each of the determinations).

Journal of the Franklin Institute				"Recueil de constantes physiques"		
	Investi- gator	Distance km	Velocity		v (centa- mètres par seconde)	Auteurs
1 2	Cornu Perrotin	23 12	299,950 299,900	6 7		Fizeau, 1849 Cornu, 1871- 1874
3	Michelson Newcomb	0 6 6 5	299,895 299,860	8 9	2 9988 2 980	Perrotin, 1904 Foucault, 1819~1862
5	Michelson	35 4	299,820	10	2 9994	Michelson et Newcomb, 1885.
				11	2 9989	Michelson, 1902.

In order to dispel my perplexity, I had recourse to the original communications, memoirs, papers, etc, and to my amazement I found that of these 11 determinations, only one appears to be correctly quoted, or, at any rate, is in accordance with the

original contributions !

(1) Cornu's value is 300,400. The value 299,950 is evidently the result of a later discussion of Cornu's own results Apart from the fact that it appears questionable to quote as the result obtained by an investigator, a value to which he himself emphatically objected (Rapports présentés au Congrès International de Physique, 1900, vol 2, p 228), the value given is different from that given by Helmert (Astronomische Nachrichten, vol. 87, 1876–1878, p. 123) and from that of Listing as quoted everywhere else by Newcomb (Astronomical Papers for the American Ephemeris and Nautical Almanac, vol. 2. Pt. 111.). by Michelson himself (Decennial Publications of the University of Chicago, vol. 9, 1902, and Phil. Mag, 6th series, vol. 3, p. 334), and by others, namely, 299,990. I have not yet been able to find Listing's original paper and cannot offer any reason for the discrepancy.

(2) The distance given is that between the Nice Observatory and La Gaude, determinations over which gave 300,032. The value given (299,900) was obtained between the observatory and Mont Vinaigre, a distance of 45,950 7 metres, not 12 km. (Annales de

l'Observatoire de Nice, vol. 11, 1908)

(3) This value does not agree with any other value given in any contribution by Prof Michelson, the existence of which I have been able to ascertain corresponds closely to (11) (see below).

(4) The distance is wrong, this particular value was obtained between Fort Meyer and the Washington Monument, a distance of 3721 2 metres, not 65 km (loc. cit.)

(5) This value was correct at the time of publication. It has been since reduced to 299,802 (Astroph.

Jour., vol. 65, 1927, p. 2).

(6) Fizeau's result (for air) was given as 70,948 leagues of 25 to the degree. The "Nouveau Larousse Illustré," the standard French encyclopædia, gives 4444 inetres for the value of the "lieue de 25 au degré." This gives 315,300 nearly (Comptes rendus,

vol 29, 1849, p 90).

(7) Cornu's determination, as given, was obtained between Sept. 3 and 27, 1874. That obtained in 1871-1872, namely, 298,500, was altogether rejected (Annales de l'Observatoire de Paris, vol. 13, 1876).

(8) Perrotin's experiments giving this figure were made in 1902, not in 1904. It is only a preliminary result; the final value was 29990 (Annales de l'Observatoire de Nice, vol. 11, 1908).

(9) Foucault made no determination of the absolute velocity of light in 1849; all the work was done in the summer, 1862 (Comptes rendus, vol. 55, 1862, p.

(10) With the exception that Newcomb did not co-operate in these experiments, that they were performed in 1879, and that the result was 299,910, the data given are correct (Astronomical Papers for the American Ephemeris and Nautical Almanac, vol. 2,

(11) No determination appears to have been made by Michelson in 1902. The value 299,890 was adopted by him in a paper published that year, as representmg the best value up to that time, and is the average of several determinations by Cornu (discussed by Listing), Newcomb, and Michelson (Decennial Pub. Univ. Chicago, 1902, and Phil. Mag., 6th series, vol. 3, p. 334).

Nor is this all the tale: Newcomb (loc. cit.) states

that Cornu's first experiments were made in 1874, and his final ones in 1878, and this is repeated by Michelson, by Preston ("The Theory of Light" and by Cornu himselt (Rapports présentés au Congrès International de Physique, vol 2, p 227). Here is a physicist misled into giving a year four years in error for the time of his own experiments!

Finally, Michelson gives, as having been obtained in 1925 (Astroph Jour., vol 65, 1907, p 12, first line of the first table), a result, namely, 299,802, which had already been published in 1924 (loc. cit vol 60,

1924, p 256).

I shall not trouble readers of NATURE with the misprints which only offered a temporary check.

Some may think that I have been too exacting in respect of dates as they seem immaterial in the determination of a constant Let it be remembered that a velocity involves the use of a unit of time, and that so long as this unit is provided by the rotation of the terrestrial globe, it is apt to vary, and this variation cannot be ignored in measurements involving an incredibly small fraction of a second of time (one fifteen millionth in the case of Foucault). In few cases only is the actual date given in the original contributions from the investigators, the average time of the year has often to be guessed.

M. E. J. GHEURY DE BRAY.

40 Westmount Road, Eltham, S.E 9.

#### Prof. Lewis's 'Light Corpuscles.'

In order to maintain his theory of light corpuscles (see Nature, Feb. 13. 1926), Prof G. N. Lewis has had to suppose that the absorption of a quantum, as an event, has a certain control over the emission of that quantum. This is repugnant to common sense, and remains so even when qualified in the way Prof. Lewis has been able to do.

To overcome this the following suggestion may be made. When two events are causally related, as, for example, the emission and absorption of a photon, it will depend upon certain conditions whether we can say that they are in causal contact; whether the

interval between them is zero.

When, on investigation, it is found that the two events are the only two concerned in the relation, then we must suppose that they are in causal contact, this is what is supposed to happen when light is transmitted in vacuo. But when on analysis it is found that there are other events concerned, then it is by no means necessary that the two events first mentioned should be in direct causal contact. Thus it may be that the events can be arranged in series by their extensional relations, with the two original events as ends or termini; and in this case, even though each event may be in contact with the next in the series, the two ends will not be so related: and, what is more, their mutual relations will depend upon the intervening events.

This simple suggestion will easily account for the observed diminution in the velocity of light in a refracting medium, and we may hope for an intelligible explanation of the diffraction effects of a lens system. Thus the absorption-event at the photographic plate is not directly related with the emissionevent at the distant star, nor is the interval between them zero; they are connected via the chain of events occurring within the lens system of the telescope, and these latter will presumably have an effect on the final absorption event, producing in fact the diffraction pattern that is observed.

M2

At first sight this idea upsets the simple reversibility of the process, but not, I think, if we confine the postulated reversibility to pairs of events actually in causal contact: in any case it is more intelligible and more in accordance with the historical development of physics than the one it has been designed to replace or supplement

#### Penetration of Radio Waves.

In a recent letter to NATURE (July 2) by two of the present writers, it was pointed out that information was lacking as to the extent to which radio waves could penetrate the earth By the courtesy of Mr. J. H. Clark, Mr. H. K. Lidstone, and other officials of the tamous Caribou Mine, Colorado, an opportunity was offered on Aug. 17 to make some satis-

factory tests on this point.

Mr. Guy L. Allen, of Boulder, used a nine-valve (or tube) super-heterodyne Victoreen set which he had built himself, and with which he had heard Buenos Ayres, Madrid, Lima, and London. At a depth of 220 feet below the surface, and in a cross cut clear of wire, rails, and pipes, he readily detected K F E L Denver (248 metres), and the concert was well heard from the loud speaker by all present. On proceeding to a depth of 550 feet, carrier-waves were detected, yet no clear reception was possible in the morning But in the evening at 9 20 the party returned to the 550-foot level, and at the end of a tortuous passage 80 feet distant from all wires and pipes, speech, music, and song from K O A Denver (326 metres) was heard from the loud speaker about as clearly as on the surface earlier in the evening. In both cases the reception was by loop, and in both cases maximum intensity was obtained when the loop pointed within a few degrees of Denver, about fifty miles away.

Previous experiments at the tunnel at Montreal, Canada, had shown that 40 metre waves were weak in penetrating power; that broadcasting waves were more efficient, while longer waves of 10,000 metres

surpassed both.

Details of this experiment will be published in due course in a report of the Bureau of Mines.

#### Pyrex as a Container for Radium Solution.1

Some readers of Nature may be interested to know that Pyrex glass is not suitable as a container for a solution of radium salt. About two and a half years ago, I dissolved salt containing 150 milligrams of radium and put it into a Pyrex bulb connected with a Toepler pump for removing the radion. Three months ago, when examining the bulb, I found it to be cracked in almost every conceivable direction. The bulb seemed airtight still, but the solution was mmediately removed to a soft glass bulb for safety. On closer examination it was found that the cracks started from the inner surface of the bulb. Some had

 $^{\rm 1}$  Publication authorised by the Director of the National Bureau of Standards of the U S. Department of Commerce

No. 3020, Vol. 1201

penetrated only slightly, and others were nearly or completely through to the outer surface. None extended below the level of the solution. They only

appeared where the radon could be expected to collect in quantity in the evacuated region just above the solution This indicates clearly that the cracks are caused by the bombardment of the inner surface by a-rays How this starts a crack, and causes it to continue only so far as the bombardment by the a-particles extends, is not readily understood This difficulty is not confined to a bulb containing solution, for I have also observed that Pyrex tubes used to store purified radon behave in a similar manner. It has been known for some years that quartz is affected similarly, a

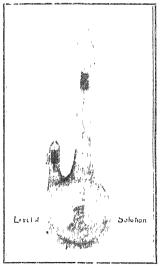

Fig 1 - Pviex bulb cracked by a-ray bombardment.

fact discovered, I believe, by Madame Curie. The accompanying photograph of the bulb (Fig. 1) shows many of the larger cracks.

L. F. Curtiss.

Bureau of Standards, Washington, D.C.

#### The Expert in the Civil Service.

Members of the professional, scientific, and technical classes in the Civil Service will welcome the leading article on "The Expert in the Civil Service" in the issue of Nature of Aug. 27. The proposal for the appointment of a Royal Commission to examine and report on the present position of the professional worker in State service has the full support of the Institution of Professional Civil Servants, a body representative of the above classes. Indeed, since its inception in 1919, the Institution has been striving to obtain an official inquiry into the conditions governing the employment of its members in the Civil Service. The Institution is convinced that the improvement of the status of professional workers in the Service—the necessary precedent to fuller economic recognition—and freer access to administrative posts, will only be obtained by such an inquiry as is advocated. An impartial inquiry into the position of the professional and scientific classes in State employment is absolutely essential if the efficiency and well-being of the Service under modern conditions are to be maintained. The Council of the Institution reiterated last year its policy of pressing for a public inquiry, and welcomes the influential support of NATURE in the steps that will be necessary to bring to pass this long-desired event, which is of such importance in the interests of both the State and the professional worker.

F. A A. MENZLER. (Honorary Secretary.)

The Institution of Professional Civil Servants, 69 Victoria Street, London, S.W.1, Aug. 29.

### Some Problems of Polar Geography.1

By Dr R N. RUDMOSE BROWN.

THE TASKS OF EXPLORATION.

THE existence of an Antarctic continent is still based on circumstantial evidence, and until more than some 5000 miles of its coastline, or only about 35 per cent. of the total length, are known, direct evidence of Antarctica will be lacking. It is not a little remarkable that all the exploration of the twentieth century has merely modified the probable outline of that continent as it was predicted by Sir John Murray in 1886. He had little but the reports of Ross, d'Urville, Wilkes, a few sealers, and the Challenger to go on, and, mainly on circumstantial evidence, he built his Antarctic The one considerable change in that continent map has been the curtailment of the Weddell Sea and the removal of its southern extremity some four degrees north of Murray's position in lat. 82° S

Most of the Antarctic 'lands,' and certainly nearly all those that may be classed as key positions to the coastline of Antarctica, date from last century, some of them from a hundred years ago Coats Land, Wilhelm Land, and Oates Land are among the few exceptions. Enderby Land, the one certain or nearly certain land in more than 3000 miles of hypothetical coastline, has never been seen or seriously searched for since Biscoe found it in 1831. It should be the base of an expedition that is prepared to work westwards. Heavy ice congestion so far found by all vessels that have tried to push south between Enderby Land and Coats Land, suggests that this stretch of coastline will have to be put in by sledge journeys along the edge of the ice cap. The western shores of the Weddell Sea are another ice-girt region which no ship has been able to penetrate, a region of dangerous ice pressure. Here, too, the advance must be by land journey, but it should be relatively simple, since accessible bases are known in Oscar Land and adjoining parts of Graham Land. Lastly, there is the great gap south of the Pacific between Charcot and Edward Lands, which leaves ample scope for an attack from both ends. A minor problem in the outline of Antarctica for an expedition based on Edward Land is the determination of the eastern side of the Ross Sea and the elucidation of Amundsen's sighting of land to the south of Edward Land, the appearance of land which he called Carmen Land.

Even more important, however, than the discovery of the 'missing' stretches of the Antarctic coastline is the explanation of the structure of the continent and its former connexions with other lands of the southern hemisphere

Graham Land and Victoria Land are both regions of lofty mountain ranges, but apparently of contrasted structure and diverse origin. The ranges of Graham Land, often called the Antarctic Andes,

<sup>1</sup> From the presidential address to Section E (Geography) of the British Association delivered at Leeds on Sept 1.

in stratigraphy and structure as well as in their eruptive rocks, bear so close a resemblance to the Cordilleras of South America that there can be no reasonable doubt that they were at one time connected and are in fact disunited parts of the same foldings Nor does it appear doubtful, any longer, that the line of former continuity can be traced by a submerged ridge on which stand relics of the chain in the South Orkneys, the volcanic South Sandwich Group and South Georgia, extending in a great arc between Trinity Land and Tierra del Fuego and sweeping well to the east of Drake There is no doubt of this line of connexion, but we are still uncertain if South Georgia, and even more so, if the Falklands are really fragments of the arc or relics of a lost South Atlantic Land.

The Antarctic Andes, or Southern Antilles, have been traced south-eastward but lost sight of at Alexander Island and Charcot Land, which in all probability are parts of the same formation. The great problem of the Antarctic is what happens to these ranges. On the opposite, or New Zealand, side of the Antarctic, the great fault ranges of Victoria Land show little if any resemblance in structure and origin to the Antarctic Andes. A great horst capped with horizontal layers of sandstone, probably of Permo-Carboniferous age, is associated with much evidence of volcanic activity, and seems to rise from a great peneplain of crystalline rocks which underlie the whole of that side of the Antarctic ice-sheet.

The structure of the Victoria Land edge of the Ross Sea is reminiscent of Tasmania and eastern Australia, and the suggestion of former continuity across the Southern Ocean receives further support from our knowledge of submarine relief between Antarctica and Australia.

The relationships between Antarctica and South Africa are still very obscure, since the African quadrant of the Antarctic, both by land and by sea, remains one of the least explored parts

One suggestion is that the horst of Victoria Land is continuous with the Antarctic Andes Certainly the direction of the Maud Mountains to the south of the Ross Sea supports this view, and evidence of great faults bounding the Andes may show that those ranges after all are not entirely different in nature from the ranges of Victoria Land. A second suggestion is that the Antarctic Andes reappear in the Ross Sea in the old crystalline rocks of King Edward Land—which as yet are but little known—and that these were once continuous with the folds of New Zealand. If this be true, the ranges of Victoria Land and the Maud Mountains probably swing across to Coats Land and may cause those vague shadowy shapes that a few of us who have seen Coats Land believe to exist in its far interior. Nothing is known at first hand of the structure of Coats Land, but rock fragments dredged in the Weddell Sea, and presumably

derived from Coats Land, suggest a closer relation with Victoria than with Graham Land

In any case, it looks probable that our knowledge of Antarctica confirms the growing belief that the Pacific basin is girdled by a ring of fold mountains marking the course of a system of geosynclines. The remains of the borderlands of this Pacific geosyncline may possibly be found in small islands in that mysterious ice-bound region to the north of Edward Land which no ship has been able to penetrate.

Much has yet to be done in explaining the peculiar Antarctic blizzards which rank among the flercest winds on the face of the globe. Dr G. C Simpson has given an explanation of these in the Ross Sea, but are the blizzards of Wilkes and Coats Lands, which occur under different topographical conditions, amenable to the same explanation, or has Prof. W. H. Hobbs found the solution in his theory of strophic winds associated with glacial anticyclones, a theory which he applies also to Greenland, where he is at present investigating it?

A further important meteorological problem, with strong geographical bearings, is the alimentation of the ice-sheet. We know that it is wasting by the calving of icebergs, by surface ablation, and other processes, and that it has shrunk considerably since its Pleistocene maximum, but we are at a loss to explain satisfactorily how the precipitation in the heart of an anticyclone can ever have been sufficient to allow such an ice-sheet to There is every reason to believe that during the great Ice Age, ice-sheets did not develop over the Arctic islands of Canada or over most of Siberia. The temperatures were low, but moisture was in-Yet in the southern hemisphere the sufficient ice grew in the heart of a vast high-pressure area

Still another problem is that of oscillation of climate as expressed by varying amounts of sea-ice and variations in the intensity of currents. R. C. Mossman and others have shown that there is a correlation between certain Antarctic records and those from places in the northern hemisphere. There seems to be every likelihood that before long general weather forecasts of real value will be possible for some months ahead. At Buenos Aires. for example, the high correlation coefficient of +0.88 is reached when the summer rainfall there is correlated with the temperature of the South Orkneys for the winter that began three and a half years earlier. In fact, statistical correlation indicates that a very cold winter at the South Orkneys will be followed after an interval of three and a half years by a drought over the Argentine cereal belt; a very mild winter, after the same interval of time, by bountiful rains.

Lastly, there is great need of oceanographical work in high southern latitudes. This branch of research has been overlooked by most expeditions in their hurry to reach their southern bases. The employment of echo-sounding should, however, make it both easier and more accurate.

No pioneer problems of equal magnitude await the explorer in north polar regions. There is small likelihood that any new land of importance remains to be discovered. There is certainly no 'polar continent.' However, there are gaps to be filled Nicholas Land, found by the Russians to the north of the Taimir pennsula in 1913, has still to be investigated. Its full extent and its relation to other Arctic islands are unknown. North-west of it the Arctic Ocean has never been penetrated except by the drifting St. Anna in 1912–14. We hope that Russian investigators of the coast of Siberia will include Nicholas Land within their scope of work.

Another problem of importance and far-reaching influence is the mysterious fluctuation in the extent of Arctic sea-ice. The fluctuations appear to be cyclic rather than progressive, but so far defy satisfactory explanation. Dr. C. E. P. Brooks has recently pointed out the influence of the amount of ice in the Labrador and East Greenland currents on pressure distribution and consequent amount of precipitation in the British Isles. Here at least is one direct link between the Arctic and the most important factor in our climate. But until we know more about Arctic climatic conditions and the distribution of ice in the Arctic basin, we are not likely to find the cause of these fluctuations.

Facts so far available point to a rotary surface movement with overflows from an overcharged Arctic basin, by the Greenland Sea and other less important outlets. This movement may account for the tendency of ice-bound vessels in the Arctic basin to take a peripheral drift. It may also explain the relatively smooth and unrafted ice reported from the vicinity of the Pole. Again, the heavy ice to the north of Greenland may be due simply to the heaping and rafting against the land of the pack that has been swept past the overflow of the East Greenland current. It cannot, however, be said that this circulation is proved.

Fluctuations in the amount of ice in the overflow currents may well be due to variations in the strength of these currents. These variations may be associated with departures from the normal in the amount of water poured into the Arctic basin from the great Siberian and American rivers, which in its turn depends on causes far removed from Arctic regions. The complexity of the problem is almost baffling, but even before the chain of cause and effect is traced, useful work could be done in looking for correlations.

#### METHODS OF EXPLORATION.

In recent years the aeroplane has appeared in the Arctic, and Amundsen and Nobile have used the airship. It was inevitable that aviation should be tried in high latitudes, if for no other reason than its spectacular daring, but so far its success has not been marked. That, however, does not necessarily imply that aviation is never to be a serious help in polar exploration. Amundsen's flight in the Norge gave a probable confirmation of what had already been deduced from indirect evidence. He found no land where none was expected. He saw nothing but ice-covered sea. Moreover, a rapid flight over snow-covered land, even if the eye could distinguish that surface from ice-covered sea, would tell little

of importance Byrd's flight to the Pole and back was of even less value to exploration, for on his track there was no possibility of land. The kind of exploration that is now required entails patient observation and accurate measurement. A quickmoving machine cannot help in this, and there is always the probability of mist to hamper the value and imperil the success of aviation in the polar summer. Amundsen himself admits that owing to "a tremendous sea of fog, in some places of extraordinary density" in the Beaufort Sea, he may have passed over islands of low altitude without seeing them. So that on the only part of its course where land can possibly exist, the flight of the Norge has left us where we were, and the field is clear for the next explorer.

Even for reconnaissance the aeroplane has doubtful value. So much depends on ground organisation, which never can be perfect in polar regions, and there is the even greater difficulty of satisfactory landing-places. In one respect, however, the aeroplane can be successfully used in polar work, that is in aerial survey of difficult country that hes within reach of a base accessible by sea transport and provided with a good landing-place. In the Antarctic, where I have pointed out the pioneer explorer still has ample scope, long-distance flights may be of some value. The ice-cap offers the prospect of better landing than the pack-ice. Yet in view of its great expanse there is even less chance of retreating on foot after a forced descent.

#### SETTLEMENT OF POLAR LANDS.

During recent years, territorial claims have been made to all parts of Arctic regions that were not formerly subject to sovereignty, and even in the Antarctic great dependencies have appeared. This is an expression of the growing belief that polar regions are not merely desert wastes but have some economic resources of value to man.

There is no reason to suppose that the domestication of reindeer, starting with Siberian stock and gradually introducing the American caribou, will be anything but successful in most parts of the Canadian tundra, in the rich pasture lands of western Greenland, and the more restricted areas of Spitsbergen. All these regions have supported vast numbers of reindeer in the past, and should do so again if excessive hunting is curbed, wise game laws instituted, and the wolf exterminated, as Canada is endeavouring to do.

Alaska is said to have pasturage for 4,000,000 remdeer. Basing his estimate on this figure, Stefansson calculates that the Arctic tundras as a whole are capable of supporting about 100,000,000 reindeer and perhaps five times as many musk-ox. This is probably an over-sanguine estimate, for it must be remembered that the Alaskan herds are mainly in the more fertile valleys of the south and south-west, which have few, if any, equals in fertility in the tundras farther north; but even if we reduce the numbers considerably, say by so much as 50 per cent., there remains a possible food production from the waste Arctic lands equivalent to some 1,000,000,000 sheep, or more than ten

times the total number of sheep that Australia now supports

This would, of course, take many years to accomplish, and naturally will not occur until the temperate lands of the world are more fully occupied than at present But gradually as world population multiplies and food production has to be increased, the lands that are not fit for cereal growth will command attention by their possibilities for It is a geographical axiom that the pasturage herder must always give way to the tiller of the soil with his more intensive occupation With the extension of dry farming, there seems little likelihood of any considerable areas of temperate lands in the long run being left to pastoral pursuits. But the Arctic tundras are entirely unsuited for agriculture by unfitness of soil and shortness of summer for ripening the grain. Their advantage as pasture land is that the farmer can never displace the herdsman As the world's supply of beef decreases, the supply of venison and musk-ox flesh will come more into demand

Up to the present, the tide of human migration has flowed and ebbed on Arctic shores and has been mainly a seasonal movement, marked even in the permanent residents by a great degree of nomadism But eventually the tide of white settlement will definitely set northward, even to the Arctic seas, and in its flood destroy the present inhabitants.

It is no more presumptuous to forecast a scattered population of reindeer and musk-ox farmers in the 'barren lands' of Arctic Canada, the tundras of Siberia, and even in Greenland and Spitsbergen too, a hundred years hence, than it was a hundred years ago to suggest sheep farmers in the plains of Australia or wheat fields in the Peace Valley of Canada. Every land beyond the frontiers of settlement has been a 'never-never land' to unadventurous and unimaginative folk living in sheltered homes. But in most cases the prediction has been falsified.

The problem is one of considerable importance in the future of human settlement for two reasons. First, because there is no real evidence that the white races are suited for the tropics; that is to say, for permanent racial transference as apart from visits. All the evidence that is conclusive points the other way and suggests that only by a slow process of natural selection can the white races ever find a sure footing in the tropics. Long before that is achieved, the coloured races will have effectively occupied the warm lands. This means that the white races must turn, as in effect they have been turning for several centuries, polewards in their search for new homes. Secondly, the possibility of polar settlements affects, as I have tried to show, the future food production of vast areas which at present enter little into the economic life of the crowded populations of food-importing communities.

The only example of real Arctic colonisation that exists is that of the old Norse colonies in southwestern Greenland founded in the tenth century. At their height the two colonies must have contained between 2000 and 3000 people, men, women,

and children, scattered in about 280 farms, where they kept cattle, goats, sheep, and horses, perhaps raised a few poor crops of little account, and hunted bears, reindeer, and seals. There is no need to recall the history of these settlements, how trade with Europe gradually ceased and how the Norsemen had entirely disappeared when late in the sixteenth century communications with Greenland were reopened.

Recent Danish researches at Herjolfsnes, near Cape Farewell, have discredited the old belief that the colonies disappeared either by Eskimo extermination or by fusion with the Eskimo races seems clear, at least as regards Oesterbygd, that the Norse race maintained its racial purity and did not go native' The general reluctance of the Nordic races to mix with widely divergent stock was as noticeable then as it has been in later centuries Examination of skeletons in the churchyard of Herjolfsnes reveals the interesting facts that while clothes and ornaments, in graves of the fifteenth century, show little trace of Eskimo influence, the skeletons all show signs of rickets or other malformations and stunted growth, but no sign of racial mixture with the Eskimo. There is also a very high proportion of remains of infants and young people. Evidently, therefore, the Norse colonies, at least Oesterbygd, perished by exhaustion. Even if the climate were changing for the worst during the existence of these coloniesand such a change is by no means proved—there is no reason to suppose that the habitual meat diet failed. The cessation of communications with Europe cannot have affected the diet of the colonists to any great extent. The King's Mirror, describing conditions when the colonies were prosperous, notes that most of the settlers did not know what bread was. And what else could they get from Europe to vary their meat diet?

The conclusion is, therefore, that the Norse colonists in Greenland died out for want of new blood, or, in other words, that they were not acclimatised to their Arctic home. From this it might be argued that even the Nordics can never colonise the Arctic. Certainly no other race from

temperate climates is likely to try, since the Nordies alone show that distaste for gregariousness and that capacity for enduring solitude which are essential qualities for the task. We may even grant them a greater measure of physical enterprise and love of wandering than other people

The Greenland experiment is not, however, a sure criterion of Nordic unsuitability for the Arctic. The pastoral settlement, which is suggested, will be a slow colonisation, in which natural selection will have some say. Those suited will remain, others But the colonists will will move away or perish not be cut off from the world . they will be in close touch with it. New blood will continually flow in their veins, so that the unchecked course of natural selection which operated in the old isolated Norse colonies and killed out the more nervous and imaginative type, a type that is least adapted to the Arctic, will not have free play. There is no reason why the race should become impoverished by the elimination of its most progressive element Even though a diet solely of meat has proved wholesome enough in the case of Eskimo and some explorers, it will not be necessary for the Arctic colonists to subsist on it entirely: transport facilities will bring every variety of food to their doors. If the Norsemen suffered from insufficiency of certain ingredients in their diet, a sımılar fate will not be the lot of the colonists of the future If they died out by lack of new blood and continual inbreeding, the Arctic settlers of the future will be able to avoid that disaster.

Such is the legitimate forecast, as I see it, of the outer rim of the Arctic of the future with its prosperous, though scattered, colonists of pastoral interests, and its fur farms here and there supplying high-priced Arctic furs in limited numbers. But the settlement must wait until the pressure of population on the world's resources is even greater than it is to-day. The remoter parts, those without rich tundra and the ice-covered seas and lands, must remain deserts, visited only by roving hunters and occasional explorers. In short, I see a shrinking of the Arctic wildernesses, but never their disappearance.

# The Structure of Silicates. By Prof. W. L. Bragg, F.R.S.

AT a time when the fundamental conceptions of the structure of matter are being changed so rapidly, when every six months witnesses the birth of a new analytical method of dealing with the very foundations of our physical science, the study of the crystal patterns of silicates must seem a trivial matter. Yet similar studies have played their part in the extraordinary development of physics in the last decade, and I hope that the refinement of our methods of analysis, such as is represented by the present examples, will in turn prove to be of use.

The results of the particular investigations which I propose to describe are interesting in themselves

Discourse delivered at the Royal Institution on Friday, May 20.

because the silicates form so large a proportion of the earth's solid crust, and certain artificial forms are so largely used for technical purposes. I think, however, that it is right to stress another aspect of this study. We are trying to improve the technique of the X-ray examination of solid bodies, to increase the resolving power of our instruments so that we can see finer detail and deal with more complicated structures. It is at present a tedious and difficult task to discover how the atoms are arranged in these bodies; even when some experience in handling them has been obtained, one has to devote much time and concentration to each particular case. Yet every solution makes the next problem easier to attack, and when we look

No. 3020, Vol. 1201

back on the last few years' progress, I think a very real increase in power of analysis is evident as the result of the efforts of many workers in this field.

It is this advancement of technique in which, personally, I am particularly interested. In trying to improve our instrument we examine with it from time to time a new type of solid body—these silicates being an example—and we describe what we see. I am not competent to discuss the discoveries we make; I can only hope that the casting of light at a new angle may be useful to those who have made a life-long study of these particular types of compound—I feel that my main contribution must be a demonstration of what knowledge it is possible to attain by careful X-ray examination.

The silicates present a highly interesting series of problems for X-ray analysis. The numerous crystalline forms have been carefully studied because of their importance to the mineralogist, and they show most interesting relationships and wide variation in composition. It is estimated that oxygen, silicon, aluminium, and iron by themselves compose about 87 per cent. of the earth's crust, and if we add four other elements, calcium, sodium, potassium, and magnesium, they amount together to 98 per cent. These are the elements that build up the compounds we are considering, and their relative proportions are a reflection of the fact that most of the earth's crust is composed of compounds of metals with silicon and oxygen.

The silicates occur as solid bodies, the atoms of which are arranged in crystalline patterns. These patterns are often very complex, and it would be difficult to attack them by general methods unless some guiding line could be followed through the intricate maze. Such a guiding line may perhaps be found in the peculiar part which the oxygen atoms play in building up the structure. Not only are the oxygen atoms the most numerous, but also they appear to be the most bulky of the units of which the pattern is woven, so that their predominant size and number make them force the other atoms to conform to certain simple and characteristic arrangements of oxygen atoms which we find occurring again and again as an underlying motif, throughout the range of such silicates as have yet been analysed. A few simple examples may help to illustrate this point

Four spheres, packed together as tightly as possible, assume a tetrahedral arrangement with one sphere standing on three others (Fig 1a). Six spheres when packed together take up a form where three of them lie on top of three others (Fig. 1b). Alternatively we may regard this arrangement as four spheres at corners of a square, with one above and one below this square (Fig. 1c), the second arrangement being identical with the first regarded from a different view point.

These very simple groupings of oxygen atoms, with an atom of some other element at the centre of the group, occur again and again in the silicates and in many other compounds. In many cases the group not only has a characteristic shape, but also a characteristic size, the distance between the

oxygen atoms having a value of about 2.5 Å.U. to

2 7 A U. In the list of common elements given above it is only sodium, calcium, and potassium which appear to break up the regularity of this group, and to force the oxygen atoms apart if placed at the group centre. The other elements appear to fit comfortably into the interstices of the oxygen grouping. Since there is a common distance throughout between oxygen atoms, certain atoms of one group can at the same time form part of the next group, and so a continuous structure is built up which may be thought of as a pattern of oxygen atoms with the metal and silicon atoms in its interstices

This predominance of the oxygen atoms greatly simplifies the analysis of the structures, and makes it easier to visualise the relationships between

different types All these bodies build up a crystalline pattern repeated again and again to space. Now the simplest types of pattern are those such as children are taught to make, when blocks of the same shape and size, but coloured differently, can be stacked together in geometrical designs The silicates present rather a fascinating analogy to these kindergarten patterns, the oxygen atoms being the

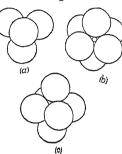

Fig 1—Groups of four, and of six, oxygen atoms Such groups, with atoms of silicon or one of the metals at the centre, are repeated indefnitely in the silicate structure

blocks and the other atoms the colouring agent. It is as if a complex pattern were embroidered by the other atoms upon a simple underlying fabric of oxygen atoms.

The two types of group, four-fold and six-fold, illustrated in Fig 1 are composed of oxygen atoms equidistant from their neighbours. We have seen that they may be regarded as spheres compressed into the smallest possible space. Such an arrangement can be continued indefinitely, and if it is done regularly one or other of two characteristic groupings of spheres is the result. These are the well-known forms of cubic and hexagonal close-packing.

This close-packing of the oxygen atoms is a very simple arrangement, and it is interesting to find that a number of silicates are based on it. Its existence in a silicate can be surmised by noting how much volume there is to each oxygen atom in the whole structure. If the oxygen atoms are packed together closely, with 2.7 Å U. between their centres, it is easy to calculate that each atom occupies a minimum volume of 14 (Å U.3). (If magnesium and iron are present, they expand this volume slightly by an amount for which allowance can be made.) Further, the refractive index, if ideal close-packing exists, must not be less than 1.7, as the oxygen atoms have a high refractivity.

Using these tests, it appears probable that certain compounds are based on one of the forms of close-packing, and we have examined some of these cases. The close-packing of the oxygen atoms is, however, exceptional, and although in most compounds the

fourfold and sixfold groups form the basis of the pattern, this pattern may be of an open type. The various forms of silica, to the investigation of which the Royal Institution has made so large a contribution, are beautiful examples of open patterns built of the four-fold groups, and other examples of these lace-work open patterns have been analysed. The closely woven patterns have been chosen for de-

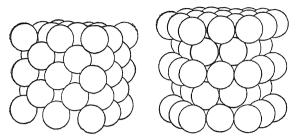

Fig 2 -Spheres in cubic and hexagonal closest-packing

scription here because their basis is the more simple.

In order to understand these frameworks of oxygen atoms, with metal atoms packed in the interstices, it is necessary to bear in mind some of the geometrical laws of pattern-making. If a repeated pattern be formed by stacking together blocks of the same size and shape, but different in colour, the unit of the pattern will be composed of a whole number of blocks. It is always possible to outline the pattern with a series of unit cells, each of which just contains one complete example of

the pattern and no more. The unit cell may be a large and distorted one if the pattern is complex, but it must always obey one condition. If one corner is placed at the centre of a block, all the other corners will also be at centres. The crystals which are based on one of the close-packed arrangements of oxygen atoms must have a unit cell related to the close-packed arrangement in this way.

Disthene or cyanite, Al<sub>2</sub>SiO<sub>5</sub>, is an example of such a crystal. Its unit cell could not well be more irregular. Its edges, and the angles between them, are all unequal, as shown in Fig. 3.

Yet its high refractive index (1.72) and small volume per oxygen atom (15.0 Å.U.3) hint that the oxygen atoms are in one of the forms of close-packing. An X-ray examination has proved this to be the case. The packing turns out to be of the cubic type, and the way the disthene cell and the cubically arranged oxygen atoms 'fit together' is shown in Fig. 3. The cell of disthene contains twenty oxygen atoms, and the cell outlined in the right-hand figure contains exactly twenty close-packed spheres. This very complex pattern of disthene has to be woven into a basis of twenty

oxygen atoms, since a multiple of five is demanded by the chemical formula. The irregular disthene cell is the way chosen by Nature of blocking out suitable groups of twenty oxygen atoms from the very simple cubic structure

When the scattering of X-rays by the crystal is examined, the close-packed arrangement of oxygen atoms shows up strongly. We can consider the effect on the X-rays as composed of that due to the oxygen atoms on one hand, combined with that due to the atoms of metal and silicon on the other hand. The former leads to a simple and intense diffraction pattern, to be expected from a straightforward cubic face-centred lattice. The aluminium and silicon atoms, which form a complex embroidery on a large scale woven into the oxygens, give a complex diffraction pattern within that due to the oxygen atoms alone. Fig. 4 illustrates the point.

The complex inner pattern contains the information necessary to tell us where the aluminum and silicon atoms are. It is a difficult matter to unravel its story, but it is by no means so formulable as it would have been had we not known that the oxygen atoms are nearly in this simple arrangement, and that the aluminum and silicon atoms are somewhere within the four-fold or six-fold groups of oxygen atoms.

As another example of this pattern-weaving, the series of compounds Mg<sub>2</sub>SiO<sub>4</sub>, MgO<sub>2</sub>H<sub>2</sub> (Mg<sub>2</sub>SiO<sub>4</sub>)<sub>2</sub>, MgO<sub>2</sub>H<sub>2</sub> (Mg<sub>2</sub>SiO<sub>4</sub>)<sub>2</sub>, MgO<sub>2</sub>H<sub>2</sub> (Mg<sub>2</sub>SiO<sub>4</sub>)<sub>4</sub> may be examined. The dimensional relationships between these crystals (the chondrodite series) have long

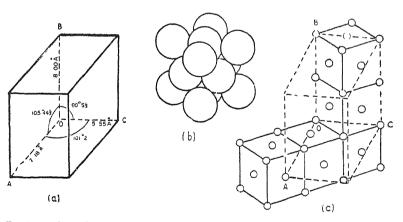

Fig. 3—(a) shows the unit cell of disthene; (b) is a portion of the array of spheres in cubic close-packing, (c) shows to the same scale a more extended portion of this array, the centres of the spheres alone being indicated. The unit cell of disthene is also a unit cell (containing twenty points) of the cubic lattice, thus is proved by the way in which OA, OB, OC correspond in length and direction in (a) and (c).

aroused interest. If we measure the unit cells of the compounds we find that two axes, outlining one face, remain constant throughout all four crystals. The thickness of the cell measured perpendicularly to this face increases in regular steps in the last three compounds, as if blocks of magnesium silicate were being added on in a regular way. With the aid of X-rays this process can be followed out in detail, and some finer points of it are not without interest. All the compounds prove to be based on hexagonal close-packing, and with

the aid of this guiding feature, Mr West and Mr. Taylor, who have been working on these crystals in my laboratory, have, in my opinion, succeeded in elucidating the approximate positions of all the

Fig. 4 —Rotation photograph around b axis of distince (right) compared with ideal rotation photograph around cube edge for close-packed atoms (left)

atoms in these complex patterns. Their results are shown in Fig. 5

These patterns are very formidable unless one has made a special study of them. However, the figures may perhaps make clear the main points We have to explain the way in which the unit cell varies in size from compound to compound, and we have also to explain a curious complication Whereas  $Mg_2S_1O_1$  and  $MgO_2H_2$ (Mg<sub>2</sub>S<sub>1</sub>O<sub>1</sub>)<sub>3</sub> have a rectangular cell (orthorhombic), the other two compounds are built on a slant with the type of symmetry called monoclinic. The blocks are not clapped directly on top of each other, but are stepped sideways It is fascinating (to the enthusiast) to see how naturally the results follow from the arrangements shown in the figure.

The circles in Fig 5 represent the oxygen atoms which form the framework on which our whole structure is based Two layers of such atoms are shown, representing two sheets of spheres packed closely, one lying on the other Some of the oxygen atoms are linked together to form a group SiO<sub>4</sub> with a silicon (not shown) at its centre. These groups are shown as tetrahedra in the diagram, and six or three edges of each tetrahedron are drawn, depending on whether its apex is turned towards or away

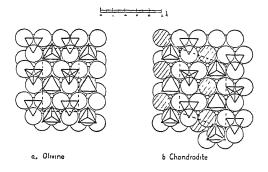

from the observer. The magnesium atoms are left out of the diagram for the sake of simplicity; the shaded pairs of oxygen atoms are to be labelled 'OH,' since they must belong to the hydroxyl groups.

Each crystal is a series of alternate strata of magnesium silicate and magnesium hydroxide.

That part of it which is magnesium silicate is arranged exactly like the pure magnesium silicate shown in Fig. 5a The layers of hydroxide cement together the blocks of magnesium silicate. In

order to outline the unit cell of any of these patterns, we join up four points in the pattern which are exactly alike. The diagram will show that the measured unit cells, shown by dotted lines, are exactly those cells which satisfy these conditions Chondrodite, MgO<sub>2</sub>H<sub>2</sub> (Mg<sub>2</sub>SiO<sub>4</sub>)<sub>2</sub>, must have a slanting cell, the next compound, humite, a long rectangular one, and the last, clinohumite, again a slanting cell. We were surprised in making our X-ray examination to find such a curious difference

in the shape of the unit cell between humite on one hand and chondrodite and chondumite on the other hand. When the pattern was put together, however, it was clear that such a difference

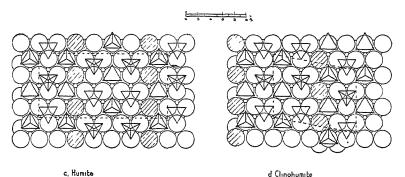

FIG 5 — Atomic arrangement of the chondrodite series of minerals (after Taylor and West). Two layers of oxygen atoms in hexagonal close-packing are shown, projected on the plane (100) of each crystal The a axes of the crystals are perpendicular to the plane of the diagram, and are practically identical for all the crystals. The diagram shows the identity of the vertical b axis in all the crystals, and the relationships in direction and length between the c axes.

followed naturally from the relative numbers of silicate and hydroxide strata.

Though very few examples of silicates have yet been analysed, the temptation to draw conclusions from them is irresistible. The most curious feature about the natural silicates is the immense variety in composition which occurs within one and the same mineral species Stupendous chemical formulæ have to be assigned in order to explain even approximately the relative proportions of the different elements in some well-known

It seems to me that the position becomes clearer when we consider the compounds as an embroidery of the metal atoms upon an oxygen framework. We may compare the oxygen framework to the steel girder system of a large ferro-concrete building in course of construction, which is intended to be divided into sets of flats Before the girder system is filled in, its configuration is very simple indeed Then certain blocks of it are partitioned off into sets of rooms, each comprising a flat; these flats are the more complex units of pattern in the crystalline structure. The arrangement of the rooms in each flat corresponds to the selection in our oxygen framework of certain spaces in which to put the metal atoms We can go one step further, and rent our flats to families of slightly different composition, so that a census of the whole building shows a bewildering proportion of types of inhabitants difficult to represent by a definite family formula. This is really the state of affairs with which the chemist is confronted when he attempts to give a formula to many of the silicates

Some of the very earliest structures which were analysed caused us to revise our ideas of what was meant by the 'molecule' of the chemist In sodium chloride there appear to be no molecules represented by NaCl The equality in numbers of sodium and chlorine atoms is arrived at by a chessboard pattern of these atoms; it is a result of geometry and not of a pairing-off of the atoms This is, of course, not universally true, for this absence of the molecule in solids is in general only found in inorganic compounds. It would appear, however, that the silicates are of this non-molecular type, and that in seeking to assign formulæ to them, and to the hypothetical acids of silicon on which they are based, it should be borne in mind that they are really extended patterns. The relative numbers of their constituent atoms are characteristic of the extended pattern, and essentially a result of their solid state, so that it is doubtful whether a grouping of the atoms into molecules has in this case a meaning. It will be very interesting to see what further light the X-ray results can cast on the relationships in this fascinating series of compounds.

#### Obituary.

PROF. RUDOLF MAGNUS.

THROUGH the sudden and untimely death, at the age of fifty-three years, of Rudolf Magnus, professor of pharmacology in the University of Utrecht, the world of science loses one who had for some years past been one of the outstanding figures in experimental medicine. At this moment there is nearing completion in Utrecht, and to be opened this autumn, a fine new Institute of Pharmacology, given by the Rockefeller Foundation with the primary object of widening the opportunity for and increasing the influence of his investigations. These, for some eighteen years past, have issued in an imposing series from the picturesque laboratory which Magnus had evolved, with great ingenuity, from a small monastic plague-hospital. The many who knew and admired him had thought of him carrying on his brilliant work for at least two further decades, and touching a growing circle with his ideas and his enthusiasm, under material conditions at last worthy of his genius.

Magnus is most widely known for the work which he, with a brilliant group of collaborators, has carried out during the past eighteen years on the functions of the central nervous system, and, in particular, on the reflex mechanisms involved in the assumption and maintenance of bodily posture, in normal relation to the earth's surface. He had spent several periods in British laboratories, with Schafer in Edinburgh, with Langley in Cambridge, and with Sherrington in Liverpool. From the last-mentioned association he received the stimulus which resulted in this best known and most important phase of his work. In Utrecht he had invaluable co-operation in this line of investigation from De Kleijn, Raademaker, and others; Dr. de Kleijn has won eminence as an otological surgeon without relinquishing his position as assistant in Magnus's department of pharmacology. The results of this work have appeared in a long series of papers, and have been embodied by Magnus in a masterly monograph on "Korperstellung," published in 1925. In the same year he gave a brilliant summary of the work in the Crooman Lecture to

the Royal Society.

This work on the central nervous system, which attracted physiologists and neurologists from all over the world to Utrecht, represents, however, only one side of Magnus's scientific activity Before his appointment to the Utrecht chair, he had been for a long term of years attached to the department of pharmacology at Heidelberg under Gottlieb. During this period he published a series of important papers of a more definitely pharmacological interest. Among the items of this earlier work may be mentioned his introduction of the method of studying the activity of mammalian unstriated muscle, by the simple technique of suspending the organ containing it in warm, oxygenated Locke-Ringer solution. Magnus, unlike some of the many who have since used it, always had clearly in view the true value and limitations of the method, and even in recent years his pupils were still busy with its application to isolated layers of the intestinal wall, with results leading to revision of his earlier conclusions as to the neurogenous nature of intestinal rhythm. By the use of this method also, in the Utrecht period, he and his pupils reached important conclusions concerning the significance of choline as a natural hormone of intestinal activity

It is an astonishing fact, indeed, that Magnus made his Institute a centre of world interest in experimental neurology, without relaxing his activity or his interest in ordinary pharmacology, He delivered his regular course on pharmacology, in a language newly acquired in middle life, served as a member of the commission for revising the Dutch pharmacopæia, and was one of the most active members of the two International Conferences on Biological Standards. In connexion with the latter he supervised important investigations on the standardisation of pituitary extract and digitalis, and made himself responsible for preparing the international standard sample of the latter. His laboratory, quite apart from its achievements in neurology, maintained a steady output of good pharmacological work. There he on my table, at the time of writing, lectures on "The Experimental Pharmacology of the Lungs" and on Cholme as an Intestinal Hormone" These were two of the five which he had written for delivery in America on a visit projected for next year, and he had sent them to me for a final retouching, scarcely needed, of their English idiom Presumably he had pressed himself too hard, but he left in good spirits for a holiday in Pontresma, where he died in his sleep after a day of active enjoyment.

Magnus was born in Brunswick, and, though domiciled since 1909 in Holland as a loyal and enthusiastic professor in Utrecht, he retained his German nationality and sympathies During the War he returned to Germany for some years to conduct and organise research on defensive measures in chemical warfare His strong national sentiment in no degree weakened his personal attachment to British colleagues, and he eagerly resumed the relations with British physiologists which had meant so much to him and to them, and had led them to regard him almost as one of their own community He came as a welcome guest this spring to the fiftieth anniversary celebration of the Physiological Society, and was a candidate for election to its ordinary membership. Medical science has lost a great investigator, still in his prime, and a genial and inspiring personality.

H. H. D.

#### MR. G. C. CHAMPION.

The death of George Charles Champion, coleopterist, on Aug. 8 at Horsell, Surrey, removes from the ranks of British entomologists one whose name has been a household word among them for more than half a century.

George Charles Champion, who was born in South London in 1851, began to collect and study beetles as a schoolboy, and before he was twenty years old he was recognised by the foremost coleopterists of that time as a field entomologist of more than ordinary energy and acumen A large number of species were added by him to the British fauna previous to 1878, in which year he was offered a commission by the late F. DuCane Godman and Osbert Salvin to proceed to Central America and collect entomological material for the great faunistic work which they had recently commenced. Champion arrived in Guatemala early in 1879, and during the next two years traversed

many hundreds of miles on horse- and mule-back, from the Pacific coast to the Polochic Valley opening into the Caribbean Sea— The number of insects of all orders collected by him and sent home in first-rate condition from Guatemala was truly enormous, and even greater success attended his researches in Chiriqui, Colombia, where his last two years in Central America were spent—An admirable itinerary of his travels in this region appeared in the *Entomological News* for 1907, which is reproduced with additions in the introductory volume of the 'Biologia Centrali-Americana'"

Champion returned to England in 1883, and at once found congenial work as sub-editor of the "Biologia," and private secretary to Messis Godman and Salvin Besides preparing, with the able assistance of the late Mr Arthur Cant, the vast mass of Central American Coleoptera for the collaborators in the section of the great work devoted to the Insecta, he was entirely or mainly responsible for eight volumes dealing with that order, in which upwards of 4000 species of beetles were described by him as new. Another volume on the Rhynchota is also due to him, and his share in the production of the "Biologia" is generously acknowledged by the late Dr Godman in the "Introductory Volume," which concluded the great undertaking in 1915.

Champion's favourite group of beetles was the Heteromera, and in 1895 he published in the Belgian *Annales* a list of the Tenebrionidæ supplementary to that of the great Munich Catalogue of 1869, which more than doubled the number of known species of that extensive family.

The name of Champion is especially associated with the *Entomologist's Monthly Magazine*. To the pages of this valuable serial he was one of the earliest and most constant contributors, and after he became a member of the editorial staff in 1891, his services in maintaining the high standard and character of the magazine have throughout been regarded by his colleagues as inestimable. He was also, for the last four years, one of the editors of the *Annals and Magazine of Natural History*.

In 1891, twenty years after his election as a subscriber, Champion succeeded the late Ferdinand Grut as librarian to the Entomological Society of London. He held this onerous office for nearly thirty years, and in 1893 he produced the first printed "Catalogue" of the Library, followed by a "Supplement" seven years afterwards His modest and retiring character prevented his acceptance of the chair of the Society, but in 1925 he was one of the vice-presidents. He joined the Zoological Society in 1888, and in 1897 the Linnean Society elected him one of its associates jubilee meeting of the South London Entomological Society in 1922, he was the sole surviving original member, having taken a leading share in the inception of this flourishing association Steady, thorough, and meticulously accurate in all his work, and at all times ready to assist his friends and colleagues to the utmost of his power, his death leaves a gap in the ranks of British entomologists which it will be difficult to fill

#### News and Views.

Comments have recently appeared in the piess on the possibility of a connexion between the total solar eclipse of June 29 and the unusually wet weather during this summer in Great Britain. It may, of course, be said at once that there is no scientific basis for the theory that the eclipse is responsible for the wet summer It is impossible to disprove absolutely the theory, because we cannot make the experiment of having the year 1927 over again, but without an eclipse visible in England. It is, however, possible to give sufficient reasons to indicate the improbability of any connexion between the eclipse and the persistent wet weather. In the first place there are at least two solar eclipses every year and there are no corresponding wet periods in Britain m fact. during the period 1881-1925, when there were 25 important total eclipses, the rainfall of the Butish Isles for each of the 6 months beginning with the month of eclipse was above the average in 63 cases, below the average in 83 cases, and equal to the average in 4 cases. In the month of the eclipse the rainfall was below the average in 16 cases, and above the average in 7, and equal to the average in 2, in the month following the eclipse month, rainfall was below the average in 12 and above the average in 13: in the succeeding month, i.e. the second month after the eclipse month, rainfall was below the average in 14 and above the average in 11. The effect of an ecluse, if it existed, could not therefore be of a general character, due to the earth's atmosphere being temporarily deprived of a portion of the solar radiation or emanation which it normally received.

It has sometimes been suggested that there is a purely local connexion with weather confined to the part of the earth's surface where the eclipse occurs, due to that area being temporarily deprived of solar radiation. But the area is temporarily deprived of solar radiation every night for a much longer period than that involved in an eclipse; and if an eclipse produced wet weather, night ought to produce much wetter weather. There is no evidence of any such effect. The wettest years in Britain in the period covered by trustworthy general rainfall statistics have been 1872, 1879, 1903, and 1912: the three former years were not years of eclipse in Britain, while in the latter year a partial (nearly total) eclipse was visible. The driest years have been 1870, 1887, 1893, and 1921. The three earlier years were not years of eclipse in Britain, but in 1921 there was an annular eclipse. If the references to the weather of eclipse years in Britain are examined for the period before regular statistics were collected, it is found that they vary · some eclipse years were wet, some dry. In 764, when an annular eclipse occurred in June, the year is stated to have been one of drought after long and severe frost. In 1191, again a year of annular eclipse in June, the year is recorded as a year of famine. Mr. R. Nicholls. The Bungalow. Keele. Staffs, has written referring to some records from Croxden Abbey showing that the latter half of 1330, a year of total eclipse in July, was unusually wet—The year 1598 had a total eclipse in March and is recorded as a year of great drought with very hot August—1652, a year of total eclipse in April, is recorded as a year of drought, with the "duest summer known in Scotland". In 1715 (total eclipse in May) a wet June to August followed a dry May. Thus recent statistics and historical notes indicate that the weather in Britain, in the years of eclipse visible in Britain, varies in the same way as it does in other years.

No paper which could be described as purely meteorological in character appeared in the programme of the Leeds meeting of the British Association. Meteorology had, however, a bearing on subjects discussed in at least three sections. In Section A, for example, there was Prot J. J. Nolan's paper on "Ionisation in the Lower Atmosphere," while in the forestry sub-section of Section K, Dr C E. P. Brooks contributed a paper on "Forests and Rainfall"; there was also the combined discussion between Sections A, C, and K on "The Climates of the Past" Meteorology was in evidence throughout the meeting in the form of a demonstration of weather forecasting which was given daily in the Law Library at the Town Hall. This demonstration, indeed, has now become a feature of British Association meetings. It was arranged by the Meteorological Office, Air Munstry, in collaboration with the Signals Branch of the same department. Broadcast synoptic weather reports were received locally by radio twice daily, the observations being plotted on a chart of western-Europe as they were received. From the synoptic weather charts thus constructed, forecasts for the Leeds area were prepared. The forecast was mcluded in a local daily weather report, copies of which were distributed to the various section meeting rooms and to hotels and hostels where members were accommodated. The morning and afternoon synoptic charts were also reproduced on a large scale map in the Reception Room. In addition to the demonstration of weather forecasting, a comprehensive exhibit of instruments and diagrams was arranged, illustrating the various phases of meteorological work in Great Britain. Among the exhibits may be mentioned a series of five rain-gauges illustrating recent improvements in design, an exhibit illustrating the meteorological arrangements on the London-Continental air routes, and a series of stereoscopic cloud photographs taken from an areoplane.

The most popular method of distributing electrical energy at the present time is by means of alternating currents. It is sometimes necessary, however, to have direct currents, as, for example, to charge accumulators for storage purposes, for various systems of electric traction, and for experimental purposes. This has led to the invention and perfecting of various types of rectifiers. There are mercury vapour rectifiers, thermionic rectifiers, electrolytic rectifiers, and, for small currents, crystal rectifiers.

There are also rectifiers of the mechanical type, as the commutators on direct current dynamos and rotary converters. Vibrating reeds also are sometimes used. A new and novel type of rectifier, described by Dr J Hartmann, of Copenhagen, to Section G (Engineering) of the British Association on Sept. 5, has now to be added to the list It is called a jet wave rectifier He invented the principle of it so far back as February 1907, but many difficulties had to be overcome in the college laboratory and municipal power station at Copenhagen before it could be put on the market. The rectifier utilises the fact that a jet of mercury or other conducting liquid when passing through an alternating current magnetic field assumes a wave shape which depends on the frequency of the current If this jet is falling vertically and we have two conducting blocks, insulated from one another by a thin lamina of insulating material, the plane of which bisects the waves at night angles, then it can be adjusted so that for half the period the jet is in contact with one block, and for the other half in contact with the other block. Rectification can thus be obtained. It has been found that the corroding effects of the heavy sparks which ensue can be eliminated by making the commutation take place in hydrogen By means of three such commutators working in series, Dr. Hartmann has constructed a rectifier which converts 100 kilowatts, at 550 volts, alternating power into direct current power with an efficiency of 92 per cent. The author's paper is a valuable one It is being printed in full in Engineering, beginning on Sept 9.

Outdoor substations for electric lighting supply are now becoming fairly common in England shall watch this new development with interest North Metropolitan Electric Supply Company's generating station at Brimsdown was the first to be provided with an outdoor switchgear station. It is interconnected with the Barking capital station of the County of London Co., Ltd. As the outdoor gear controls the supply, it is impossible for it ever to be completely shut down for cleaning or repairs quently, repair work must be done when one set of the bus bars, which are at 33,000 volts, is 'alive.' To reduce painting to a minimum, it has been built of reinforced concrete, which is, unlike galvanised steel, impervious to the atmosphere. The circuit breakers are controlled electrically from inside the power house In the Electrical Review for Sept 9, outdoor substations of the North Metropolitan Co. at Cuffley, Hertford, Buntingford, and Royston are described The Cuffley substation is connected with the radial feeder from Brimsdown to Hitchin at Potter's Bar. A second radial feeder commencing at Cuffley feeds in turn Hertford, Buntingford, and Royston, where the feeder is extended to the Shepreth substation of the Bedfordshire, Cambridgeshire, and Huntingdonshire Electricity Co. The switchgear is mounted on a pipe framework embedded in concrete. The transmission is partly by 33 kilovolt underground cables and partly by 33 kilovolt overhead lines. At each substation there are banks of step-down transformers. In certain cases power can be supplied to the main line through the low pressure side of the transformers. The five stations at High Barnet. Potter's Bar, Welwyn, Stevenage, and Knebworth form the first part of a large ring main distributing system, an incoming and outgoing feeder being provided at each substation.

DISEASES of the heart take a high place as a cause of mortality, the present figure for Great Britain, 142 deaths out of every 1000, being considerably more than cancer Probably not less than 40 per cent. of all deaths from heart disease are of acute rheumatic origin, of which two-thirds is contracted in the years of childhood-5-15 years The Ministry of Health has therefore been well advised to publish a series of studies on the subject, by Dr. Eastwood, Mrs. Forest Smith, Dr J E A Underwood, and Dr J Alison Glover, with a prefatory note by Sir George Newman (Reports on Public Health and Medical Subjects. No 44 London: H.M Stationery Office, 1927. 1s 6d. net) The following statements (not advanced as 'conclusions') seem to emerge from the subject matter of the report. Acute rheumatism is probably a chronic progressive infection, thought by many to be due to a streptococus of the Viridans group, of low-grade, if of any, infectivity. Poverty and urbanisation are potent predisposing factors, but dampness of environment does not seem to be an important one. Focal sepsis, e.g. in decayed teeth and tonsils, is an important factor, and removal of unhealthy tonsils has considerable value in prevention. Once the child has sustained an attack, in order to minimise the risks of permanent damage to the heart and of recurrence at some future date, it requires (a)full in-patient hospital treatment for a period of from six to twelve weeks, and (b) special convalescent treatment and after-care for a further period of at least six months.

A VERY successful exhibition was organised by the British Aquanists' Association on Sept 6-10 at the Chelsea Polytechnic, and save for a small experimental show last year was the first of its kind held in Great Britain, and the largest show yet held in the world except the Steinhart Exposition, Philadelphia, which was not confined to fishes The arrangements were admirably carried out by a committee of which Dr. H. B Jones is chairman and Mr. A. W. Croser honorary secretary The primary object of the exhibition was to demonstrate to the public how aquaria may be set up with growing vegetation so as to be independent of change of water or artificial aeration. The difficulties of producing such an exhibition as this were exceptional, owing to the fragility of the tanks, the weight of water and shingle, the transport of live fish-especially tropical onesthe necessity of transferring them from the travelling cans to the show aquana, and the fact that fish must not be subjected to any sudden change of temperature. The proceedings were opened by Mr. E. G. Boulenger, who had acted as principal judge of the exhibits entered for the Haig Challenge Cup and numerous medals and diplomas. The Association includes members in Japan, China, America, and all over Europe; some of the fish on exhibition had travelled as far as from Glasgow. The 350 aquaria contained approximately 20,000 gallons of water, and about 8 cwt of shingle, totalling a weight of nearly 176,000 lb. More than 20,000 aquatic plants, apart from those entered for competition, were used to furnish the tanks.

The Heibert Spencer Lecture for 1927 was delivered at Oxford by Prof S. Alexander, who took as his subject "Art and Instinct", and the lecture has recently been published by the Oxford University Press, price 2s net Prof Alexander raises the question as to whether there is a specific esthetic emotion, or whether the asthetic attitude is nothing but ordinary feelings or attitudes towards the subjects of art in a certain condition of refinement and complication. If the claim for a peculiar æsthetic emotion is to be maintained, it must be traced to some impulse in human nature. Herbert Spencer derived art from the play instinct, and Burke from the instincts of self-preservation and of society, including therein sex After reviewing the attitude of Hume and Kant, Prof. Alexander submits that the æsthetic impulse and the æsthetic emotion accompanying that impulse are an outgrowth from the impulse of constructiveness, and are that impulse when it has become first human and next contemplative. With regard to instinct in general, he follows Prof. McDougall in his use of the word and also in looking upon constructiveness as an instinct. Between animal constructiveness and artistic production there is an intermediate stage of handleraft in which constructiveness remains practical but is humanised for a purpose. Purpose can only arise in a creature which possesses ideas and has memory.

PROF. ALEXANDER thinks that animals have 'construction' in a specific sense: in man it is more general, and might better be called 'synthesis' or 'constructional.' This synthesis, with its accompanying analyses, is the most obvious feature of science of all kinds, and so science may profitably be treated in its kinship with art; but while the lover of beauty adds his personality to Nature, the man of science sets himself by a supreme exercise of personality to keep his personality out Constructiveness becomes art when it ceases to be merely practical. When an object has been constructed it is there to be observed and can be used as the satisfaction of the constructivepassion itself. The passion takes possession of its object and lifts it out of practical consideration. It is not play, for play is still the shadow of practice. It is the constructiveness of play from which art is descended, and not the playfulness of it. Artistic construction is compelled in the artist by the excitement which certain subjects provoke, and he is at a certain remove allied to his brother the nightingale and his humbler and dowdier brother the beaver.

Yet art does add to the world a fresh reality even though based on ordinary reality. The lecture will interest all those concerned with psychology and with the theoretical and scientific aspects of art, but Prot. Alexander has not minimised the difficulties of the problem, and his readers cannot but feel that "much yet remains to be said."

An illustrated pamphlet has been prepared by the Ministry of Agriculture in conjunction with the Home Office to indicate the nature of the risks associated with farm machinery and to afford guidance as to the precautions necessary to secure proper standards of satety in connexion with its working (London · H.M. Stationery Office. 9d). Machinery of various types is considered, but stationary engines, transmission and barn machinery are dealt with in particular detail. Attention is directed to the importance of proper lighting and spacing in preventing accidents as well as to the necessity for efficient safety appliances, which may usually be obtained at a moderate cost. Steam boilers, electric and suction gas generating plants are briefly discussed and precautionary measures with regard to the storage of petrol or other inflammable spirit provided. Finally, the necessity for proper instruction of persons engaged in working the machinery, and the importance of having first aid requisites available is urged. A leaflet (No. 177) has also been added dealing with general precautions against accidents due to farm machinery.

SIR MURDOCH MACDONALD has been elected president of The Junior Institution of Engineers in succession to Engineer Vice-Admiral Sir Robert B. Dixon. Sir Murdoch will take office at a meeting to be held at the Caxton Hall, Victoria Street, S.W.1, on Friday, Nov. 18, when he will deliver his presidential address.

The Air Ministry has announced that a strong earthquake was recorded at Kew Observatory on Sept. 11, at 11.21 p.m. Its centre is estimated to have been 1700 miles away from the Observatory. There were two further shocks of much smaller intensity in the early morning of Sept. 12 Press messages report the occurrence of a severe earthquake in South Russia with a centre in the Crimea.

The study of the divining rod is being pursued by professors of geology and other men of science occupying positions of recognised importance in the universities of Central Europe  $\Lambda$  meeting of the Internationaler Verein der Wunschelrutenforschers is to be held at Hildesheim in October next, when a series of experiments will be conducted under the supervision of Prof F. Schoendorff. The results obtained will be published fully in the Zeitschrift of the Society

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A pathologist at the East Suffolk and Ipswich Hospital—The Secretary, The Hospital, Ipswich (Sept. 19). An

analytical chemist in the Medical Department of Tanganyika Territory with experience of foods and drugs analyses in a borough analyst's or similar laboratory—The Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S.W 1 (Oct. 1) A microbiologist for research work on sewage disposal problems—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Oct. 3). A junior technical officer for the Air Ministry Technical Development Staff—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (Oct. 5). A student probationer

for work at the Plymouth Laboratory—The Director, Marine Biological Laboratory, Plymouth (Oct 12). A physiological botanist and a biochemist for research work on cotton to be carried out at Coimbatore—The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (Oct. 29). An agricultural botanist (male) as head of the biological department of the Seale-Hayne Agricultural College—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon—A few civilian education officers, Royal Air Force—Secretary, Air Ministry, Adastral House, Kingsway, W.C.2.

#### Our Astronomical Column.

A Nova or Variable in Aquila —Plates taken at Konigstuhl Observatory by Prof. Max Wolf on July 30 and 31 showed a star of the ninth magnitude in the position (1927 0) R A 18h 52m 11 85°, S Dec. 3° 24′ 59 8″, which did not appear on twenty-five plates of the region taken between 1892 and 1926 On Aug. 17 its brightness had increased by half a magnitude. It appears on plates taken at Harvard Observatory on June 27, and also on one taken by J. Voute at Bandoeng on June 25, when its magnitude was 7 5, so that there appear to have been fluctuations of light. It was absent from a Harvard plate on June 8, being then below mag. 11 5. It was brighter visually than photographically in August, being fully of magnitude 8.

Prof. Wolf considered that the spectrum was of nova type on Aug. 17 P Guthnick and R Prager examined the spectrum with the 122cm reflector at Babelsberton Aug 19, when the hydrogen line H was seen and also numerous absorption bands Bright lines were suspected in the yellow and green, but they may have been merely the spaces between absorption bands. The character of the object as a nova is not yet definitely established, it may be an irregular variable. It is well placed in the evening sky and within reach of small instruments, so it should be followed.

GALE'S COMET.—Mr H. E. Wood, who has just returned to Johannesburg after a visit to England, has sent some further observations of Gale's comet, made there by Dr Innes; he has deduced from them an elliptical orbit, with a period of 11 86 years, equal to that of Jupiter. Dr A. C. D. Crommelin has reexamined the orbit, using an arc extending from June 22 to Aug 9, and confirms the ellipticity, the period found being 131 years, and perihelion passage June 14; the other elements do not differ much from the parabolic ones lately given in this column indicates that it is a member of the Saturn family, of which only three members were previously known; these are 1846 VI. (Peters) 1858 I. (Tuttle), and 1913 III (Neujmin), their periods are 1338, 13.51, and 18 years—Tuttle's is the only one that has been seen at more than one apparition. The addition of another member to this small family is therefore of considerable interest. Since it was bright enough to be detected by Mr. Gale with a binocular, it is rather surprising that it escaped detection at earlier returns, but the brightness of comets is subject to capricious variations, so it may have had an unusual increase of light at this apparition

METEORIC FIREBALLS.—Mr. W. F. Denning writes: "Reports have been received of two very large meteors observed from Somerset on Sept. 7 last. The first was noticed at 6<sup>h</sup> 3<sup>m</sup> P.M. (G.M.T.), when the sun

was shining It moved in a direction from east to west in a perfectly horizontal flight occupying about 7 seconds and was of a bluish-green colour. The object was very bright, and distinctly outlined on the clear blue sky There was no train left It was seen by Mr J. E D Beresford, Henstridge, Somerset

Somerset

"The second meteor was observed at 9<sup>h</sup> 25<sup>m</sup> PM.

(G.M T), and was a very fine object which traversed a nearly horizontal course from north to south, and showed a slight inclination toward the horizon immediately below the planet Jupiter. Its path was about 25° and duration of flight 3 seconds. It left a bright train of sparks. The observation was by Mr. A. Vowles, Minehead, Somerset.

"These brilliant meteors may very possibly have been derived from one or more of the systems which

"These brilliant meteors may very possibly have been derived from one or more of the systems which supplied the numerous fireballs reported from various parts of England in September 1926. Further observations will enable this point to be definitely ascertained"

According to letters which have appeared in the *Times*, these objects were observed over a wide area including Heathfield (Surrey), Seaford and Arundel (Sussex), Carisbrooke (Isle of Wight), Portland (Dorset), and Dinard.

EXCEPTIONAL STARS—Prof. H. N. Russell contributes a paper on this subject to the Scientific American for September—He notes that stars that differ from the general run, either by great brilliance or extreme faintness, are of special interest, and the most likely to add to our knowledge.

The stars of exceptional brilliance (absolute, not apparent) can now be detected by spectral peculiarities, or if Cepheid variables, by their period of light-change. The article states that the most luminous known star is a variable, S Doradus, in the lesser Magellanic Cloud, at a distance of 100,000 light-years; at brightest it gives 500,000 times the sun's light; one star in 200,000 gives 10,000 times the sun's light.

The extremely faint stars are much more common in space, but the difficulty of finding them is that they are only visible when they are near neighbours of the sun; even then they are generally very faint objects on photographic plates. They are singled out by their large apparent motions, which are revealed by comparing two plates of different date in a Blink micrometer. The most extreme of them was recently discovered in Virgo by Prof. Max Wolf at Heidelberg. Its proper motion is 4.84" a year, and Van Maanen has found that its parallax is 0.404" which makes it the third nearest star known, if we group Proxima and Alpha Centauri as one system. Its apparent magnitude is 13.5, from which it is calculated to give one fifty-thousandth of the sun's light or one twenty-five-thousand millionth of the star in Dorado.

#### Research Items.

POTTERY FROM TRUXILLO.—The Field Museum of Natural History has issued as No. 1 of Volume 2 of its Memoirs in Anthropology a preliminary report by Prof. A. L. Kroeber on a journey of archæological exploration in Peru on behalf of the Museum in 1925. Most of the exploration was carried out in the coastal areas of central and southern Peru; but this first part of the report deals only with the pottery art of the northern coast region in the vicinity of Truxillo. Here are the important prehistoric sites of Chanchan and Moche, the former the largest rum in Peru, the latter containing the highest pyramid, at least in the northern part of the country. Adjoining Truxillo to the north is the valley of Chicama, from which many of the specimens examined may have come though now labelled Truxillo. Truxillo is one of the centres yielding the Chimu type of pre-Hispanic pottery, for long the type, apart from Inca, best known outside Two varieties are recognised, one red and white classified by Uhle as proto-Chimu, the other black (sometimes coloured) known as Chimu. Three other types are also distinguished, which seem to point to an intercalation of influence from Tiahuanaco between the two styles. Nothing of true Tiahuanaco style or of red-white-black geometric has been discovered north of Truxillo. Prof. Kroeber's researches have been directed towards the problem whether the proto-Chimu style died out under outside influence, or whether it survived, as seemed likely, in attenuated form and was revived as late Chimu; but he has not arrived at more than tentative conclusions. He is inclined to regard the three colour geometric as later than Tiahuanacoid, while Dr. Uhle is disposed to regard it as earlier. His investigations lead to the conclusion that the proto-Chimu and Chavin styles are contemporary pre-Inca, showing traceable relations with the northern interior. Three colour geometric, a problematical middle Chimu, and the tripod and modelled styles are Tiahuanacoid and presumably pre-Inca, while late Chimu probably began in pre-Inca and continued into Inca and colonial times.

SUTHERLANDSHIRE SALMON.—In a report on the salmon from the River Hope and Loch Hope in Sutherland (Fisheries, Scotland, Salmon Fish., 1926, 7. Edinburgh and London: H.M. Stationery Office), Mr. G. H. Nall remarks on the results of the examination of 187 sets of scales collected during the years 1920-1925. A striking feature was the large percentage of fish that had spent three years in the river as parr, being 42 47 per cent., as against 6 per cent. among fish examined in 1920 from Thurso Bay. A further interesting point was the unusually large proportion of fish whose scales bore spawning marks. Amongst these was a male salmon, taken from Loch Hope on Aug. 17, 1921, weighing  $17\frac{3}{4}$  lb., which after spawning in its sixth year had returned to the sea, where it remained for two years before once more entering fresh water to spawn in its ninth year. This is the first example known to the Scottish Fishery Board of an Atlantic salmon, after once spawning, missing two complete years before returning from the sea to spawn in the third year, presuming that the scale reading was correct.

THE CALIFORNIAN SARDINE.—The sardine fishery in California which originated as a great fishery during the stress of war, has undergone striking development, and the industry has shown a vitality which augurs well for its permanence so long as the raw material is obtainable. The amount caught

exceeds by far that taken of any other species in California, and there appears at present no other which is capable of the tremendous yield, unless it be the unused anchovy. It has been recognised by the Fish and Game Commission of California, from experience with older fisheries, that rational use demands a knowledge of at least two things. There must, above all else, be information from time to time regarding the manner in which the species is withstanding the strain of the fishery. But there must also be an understanding of the natural changes in abundance which inevitably occur, so that these may be distinguished from the effects of overfishing and also may be foretold and understood. Based on such knowledge, regulation and exploitation may be rational and restrained. Fish Bulletin, No. 11 (California State Printing Office, Sacramento, 1926), includes five papers which are the first of a proposed series describing the initial results of the attempt of the Commission to establish a logical and adequate system of observation of the important fisheries of the State. Students interested in the collection and interpretation of statistical data on commercial landings of fishes will find much instructive information in these papers, including a study of the adequacy of various systems of sampling sardines which are used at Monterey.

THE LIMITS OF GROWTH.—In an essay (pp. 36. Jena: Gustav Fischer, 1927) on the limits of growth, Prof Richard Hesse seeks to establish the thesis that body size is a function of the surface of the gut. He brings forward many examples from the lower Metazoa in support of his view, e.g. the varying extent of the branches of the gut in ectoparasitic trematodes of different sizes, to show that in the organisms cited progressive increase in the gut surface. produced by branching, is associated with progressive increase in the size of the body. He cites a series of earthworms with a similar purpose, pointing out that the increase of gut surface is brought about chiefly by the formation of a typhlosole. In the small Allolobophora tetrædra this is a simple elevation, but in the stout Lumbricus terrestris the typhlosole is strongly developed and much folded. Prof. Hesse does not remark upon the absence of typhlosole in the largest of all known earthworms—*Megascolides australis*—which may attain a length of seven feet. The intestine in this worm is large, and possibly its surface, even in the absence of a typhlosole, is as proportionate as in Lumbricus to the size of the body, but it would be interesting to have data on this point.

Foraminifera of the Genus Lepidocyclina.—In the Proceedings of the U.S. National Museum, No. 2680, vol. 71, art. 8, Dr. T. Wayland Vaughan, of the Scripps Institution of Oceanography, La Jolla, California, describes some large and interesting foraminifera of the genus Lepidocyclina belonging to the sub-genus Lepidocyclina in which the two mitial embryonic chambers are characteristically of equal or sub-equal size, and are separated by a straight wall. Lepidocyclina Forresti is a new species from the Oligocene, originally found near Lynch Point, Antigua, where it was collected by Mr. W. R. Forrest in great abundance, packed closely in a cream-coloured, finely granular limestone. The species seems to have a wide range in the Antigua formation. Both microsphæric and megasphæric forms occurred, the former having a diameter of 18 mm., the latter 9 mm. to about 13 mm. A new variety of Lepidocyclina Mantelli (Morton) Gumbel is also described, and the

question raised as to whether the traditional form is the true L Mantelli or the new variety, which apparently occurs in the original locality of that species. Good microphotographs of all the forms studied, including surface views and sections, are given.

Animal Light and Symbiosis —Prof. Paul Buchner ("Tierisches Leuchten und Symbiose," pp. 58. Beilin Julius Springer, 1926) has published an address on this subject which he delivered at Lund in 1925. He points out that the history of the subject is short, for it began some fifteen years ago with an observation by Dubois on the luminous secretion of the boring bivalve Pholas dactylus. Prof Buchner considers first the light-producing organs of Pyrosoma, in which, as Pierantoni showed, the presence of micro-organisms is clearly demonstrable. The spores of this organism can be traced through the follicle cells surrounding the egg into transport cells, which are later found interspersed among the cells resulting from the discoidal cleavage of the egg, which occurs while the egg is enveloped by the follicle cells. When the first four individuals (ascidiozooids) of the new colony are formed, the new luminous organs, a pair in each individual, are formed from the symbiont-laden cells, that is, from maternal body cells. Examples are given of infection of the eggs of insects, eg Aleurodes, by transported symbionts. The luminous organs of fishes (e.g Anomalops) and those of cephalopods are described. Special attention is directed to those of Sepia elegans and S. officinalis—the organs known as accessory nidamental glands. These exhibit gland-like invaginations which form intertwining blind tubes in the lumen of which the bacteria live. Three kinds of tubular ingrowths are distinguished-white, yellow, and orange, but only the yellow ones send out light. Their bacteria are being investigated by cultural methods. The author has appended references to the original memoirs cited and has added remarks on many of them. The address gives a clear, concise, and interesting review of the present position of the

Drosophila Cripples.—A Mendelian character which is of especial interest on account of its wide range of variation has been studied by Prof. Taku Komai (Memoirs Coll. Sci., Kyoto Imp. Univ., Series B, vol. 2, No. 5) in Drosophila. This mutation expresses itself in a number of abnormalities of the middle and hind legs and its expression varies according to the condition of the food. The abnormality is called 'crippled' and is recessive, but it may fail to appear even in the homozygous state. The pairs of legs are quite differently affected, the front legs remaining unaltered. When the condition appears in the hind legs (crip.-h), one or more segments of one leg are shortened, crooked, twisted, or otherwise modified When it appears in the middle legs (crip.-m), one of them is reduplicated, small or absent. High or low temperature increases the percentage of crip.-h. The latter also appear more frequently in the early part of a culture, while crip. m flies only appear towards the end. This is due to some change in the condition of the food. Thus under certain conditions of the food, the hind legs (right or left) are affected, while under different conditions the middle leg is affected in a totally different way, but only one gene is involved. The reduplication of the middle legs takes various forms, some of which are exceptions to the rules of reduplication formulated by Bateson. The division of the legs may be either in the dorsoventral or the antero-posterior plane.

Japanese Land Mollusca.—Dr. H. A. Pilsbry, who has made special study of the Japanese mollusca,

has now begun a series of papers, the object of which will be to revise various ill-understood groups as opportunity offers. The first part (Proc Acad. Nat. Sci. Philad. vol. 79) deals first with the group of Eulota fiscina Fulton, which he places in a new subgenus, Kaiaftohelix. This differs somewhat in its anatomy, as shown in text figures, from Eulota proper. These forms are not directly related to any of the Japanese species southward, but are traceable to a separate migration from the mainland. The second portion of the paper treats of the races of Eulota (Euhadra) callizona Crosse, of which the distinctions, based solely on shell characters, are illustrated on two plates.

Volcanic Rocks of Upper Burma.—Continuing his investigations of the previously little known volcanic rocks of Burma, Mr. H. L. Chhibber describes a sense of typically 'Atlantic' types of late Tertiary to recent age from a region some seventy iniles north of Mandalay (Trans. Min. & Geol. Inst. of India, 21, 1927) The stratigraphy and tectonics were studied jointly with Prof L D Stamp. The older lavas have been completely altered by weathering, but appear to have been basic. These are followed by doleritic or teschenitic intrusions, including a probable laccolith. Finally come the younger lavas, forming a plateau. Like many of the Carboniferous lavas of the Midland Valley of Scotland, these rocks contain purple augite. They range in composition from olivine basalts to mugearites, and thus offer a remarkable contrast to the typically 'Pacific' rocks of comparable age which occur in the Lower Chindwin district fifty to sixty miles to the west. The latter rocks were recently described by Mr. Chlibber in the Journal of the Burma Research Society.

THE ATLANTIS PROBLEM. — The most plausible hypothesis yet advanced in explanation of Plato's account of Atlantis appears to be that of Paul Borchardt, argued at length in Petermanns Mitteilungen, 1927 (1), and briefly summarised in the Geographical Journal for Sept. 1927. The main block of North Africa is identified with Atlantis itself, and the Sea of the Atlantes with an inland gulf once connected with the Mediterranean and now represented by the depressed belt of the Shotts which stretches inland from the Gulf of Gabes. This tract is known to have been the seat of a former civilisation, and is, moreover, still subject to tectonic disturbances. It is thought that the lesser island of Atlantis with the legendary capital and temple may have been situated within the interior basin, a view that fits in with the description by Herodotus of Lake Triton with its templecrowned island The destruction of the island by earthquake would be a startling event, but not one beyond the limits of credibility. If Borchardt's hypothesis is sound, the "Pillars of Hercules" referred to by the Egyptian priest must have been wrongly interpreted by the Greeks. With this exception—and some confusion as a result of translation is not unreasonably to be expected—the details described by Plato are satisfactorily accounted for.

AR RESISTANCE FOR SPHERES.—In the issue of the Physikalische Zeitschrift for July 1, Dr. O. Flachbart gives an account of recent observations of the resistance of a smooth sphere of 24.2 cm. diameter in the wind channel at Gottingen. These experiments do much to clear up the differences which at present exist between the results of work done on this subject in the various aerodynamic laboratories. The sphere was supported entirely by suspending wires attached to a round rod 2 cm. in diameter and 30 cm. long which prefeted from the sphere in the down-stream

direction. The results obtained differ materially from those found at Gottingen in 1923 with the suspending wifes attached to the sphere itself. They show the great influence small irregularities in the surface of the sphere such as projecting eyelets or wires or encircling rings and turbulence produced in the air by even thin wires or meshes up-stream have on the resistance

THE EARTH'S ELECTRIC FIELD —Dr. H. Benndorf communicated to the Vienna Academy of Sciences on Mar 24 an outline of a new theory of the electric field of the earth which he has worked out with the view of indicating how the present aimless measurements may be replaced by more systematic ones. He takes a surface at a height H of 20 or more kilometres above that of the earth, at which it may be assumed that practically the whole of the electric charge of the earth and atmosphere lies beneath it. The electric field  $E_{\,\mathrm{H}}$ at this surface may be taken as uniform – If  $\lambda_n$  is the conductivity and  $\lambda_H$  the mean conductivity of the atmosphere at this height, the mean earth current z is  $E_{\rm H} \tilde{\lambda}_{\rm H}$  per sq. cm, and may vary with world time but not with local time. In a tube of flow extending downward from the surface H, if at any level the field and conductivity are E and  $\lambda$ ,  $E\lambda = z$  and the two equations give  $E = (z/\lambda_{\rm H}) (\lambda_{\rm H}/\lambda)$  in which the first factor depends only on world time and the second on local time. A comparison of this result with observations leads the author to believe that the daily variation of the field over the oceans is a measure of the daily variation of the total earth current, and that the theory is likely to present a picture of the phenomena of atmospheric electricity correct in its main features.

THE ISOTOPES OF LITHIUM.—M. Max Morand has given an account in the March-April number of the Annales de Physique of a new investigation of the isotopes of lithium. Guided largely by theoretical considerations, he has designed and built a tube in which the source of positive ions, a fine point covered with a layer of salt and raised as usual to a high positive potential, gives off a homogeneous directed pencil of charged particles of considerable intensity, which are analysed magnetically. In the case of lithrum he was able to separate the isotopes, and to measure simultaneously on two galvanometers the currents due to Li, and Li, which were present in the ratio of 15 to 1 required by the chemically determined atomic weight. The mass of metal which can be deposited in this way is still small, and only of the order of 10-5 gm. for the more abundant component, but M. Morand believes that with improvements in the apparatus it will be possible to increase the yield considerably.

MAGNETIC INDUCTION IN SHEET STEEL.—It is of the greatest importance to electrical manufacturers to know the magnetic induction produced by given magnetising forces in the sheet steel used in the cores of coils. A paper (No. 545) on this subject by R L. Sanford and J. M. Barry, of the Bureau of Standards, Washington, which has just been published, will prove of great value to designers. The Burrows' permeameter is the standard instrument in the United States for the magnetic testing of sheet steel. The Fahy Simplex permeameter has advantages in the way of simplicity and convenience of operation. Its accuracy, however, has been doubted, and comparisons made over a period of four years of results obtained by the two instruments have failed to throw light on the discrepancies. The present investigation was undertaken to decide which instrument was the better and to find out the conditions under which the best results could be obtained. The authors prove that the

differences between the results are mainly due to lack of uniformity in the physical properties of the materials under test. The simplex permeameter is less sensitive to this than the Burrows, but no inherent errors were detected in either instrument. The want of homogeneity in ordinary commercial samples of sheet steel will, in the great majority of cases, be less than in the samples used by the authors. Tests made with the Burrows' permeameter are in general satisfactory. To remove uncertainty, the uniformity of the specimen should be tested, but in many cases it is not convenient to do this. The authors conclude that for the normal routine induction testing of sheet steel, the Fahy Simplex permeameter is the best apparatus at present available. The specimens tested should be made up of 10 strips not less than 3 centimetres wide.

ARCING 'IN SWITCHES -Electrical engineers have devoted great attention to the problem of suppressing arcing in switches and to appliances for breaking the electric current in a circuit. They distinguish between an arc and a spark. In an arc, the flow of current depends mainly on the ionisation of the vaporised material of the electrodes, whilst in a spark it depends mainly on the ionisation of the gas surrounding the electrodes. The spectrum of the arc exhibits the spectrum of the electrode material and is practically independent of the surrounding medium In a paper by Sven Norberg in the March issue of the Journal of the Swedish General Electric Co., a careful study is made of the breaking characteristics of switches both in air and oil. He finds that the length of the arc in air is roughly 100 times greater than in oil. In designing a 'circuit breaker,' the final length of the are is much the most important factor. As we generally want to break the circuit quickly, the distance of the break should not be much greater than the length of the arc. To reduce the length of the arc it is advisable to have two or more breaks in series. With four breaks, for example, the length of the arc is reduced to at least one quarter its value. With an ordinary lamp load, the length of the arc is not affected by the speed of the break, but with an inductive loading the length of the arc increases with the speed of the break. A current of air or oil against the arc assists in extinguishing it. A magnetic 'blow out' acts in quite a different way from ordinary blowing. It does not affect the length of the arc, but it much increases the breaking speed. The conclusions arrived at in this paper show that the designer has mastered the electrical side of the problem, but much remains to be done before the mechanical side can be

CARBONISATION OF LANCASHIRE COAL .-- The Department of Scientific and Industrial Research has issued a pamphlet (Physical and Chemical Survey of the National Coal Resources. Paper No. 9 London: H M. Stationery Office. 1s. 6d. net) on the Lancashire Coal Field dealing with the Ravine seam (Part 2). This reports carbonisation trials in continuous vertical retorts made at the Greenwich Station with the use of mcreasing proportion of steam. The yields of products show a general approach to those reported in similar tests made on a good South Yorkshire coal, but difficulty was experienced owing to injury to the retort walls, ascribed to the nature of the ash. The report was supplemented by tests made on the coke when gasified in a blue water gas plant and in a suction gas producer and by trials of both coal and coke as fuel for a Lancashire boiler. In all cases the ash of the coal gave trouble either by attack on refractory material or by clinker formation. The report is one of the most comprehensive studies of a British coal in use which has been published.

#### Calcium Therapy.

THE subject of calcium therapy was discussed at the recent meeting at Edinburgh of the Section of Pharmacology and Therapeutics of the British Medical Association. Such a discussion must, of necessity, cover a certain amount of ground in which the interest is primarily clinical; nevertheless it furnishes an interesting summary of the present state of knowledge of calcium metabolism.

Evidently the interest of those working on the subject has, for the moment, three main foci, namely, the elucidation of the actual physical and chemical conditions in which calcium circulates in the blood and exists in the tissues; the point in the system of bones, blood, and tissues, at which the parathyroid hormone exerts its influence, and the relationships existing between, on one hand, ionic calcium, and on the other, the negative ions—chiefly,

of course, Cl'—in tissues and fluids. In spite of the adverse criticism which they have received, Vines's earlier results seem to have shown quite clearly that about 60 per cent of the blood calcium is in a state which differs, chemically, from the remaining 40 per cent Other workers, using different methods, have extended and amplified this conclusion It appears that, of the 10 mgm present in 100 c c. of normal serum, 6 mgm is diffusible through a collodion membrane, while 4 mgm. is combined, perhaps with protein or lipoid, in such a way as to be non-diffusible. While interest, for the moment, centres round the diffusible form, there is evidence that the non-diffusible, no less than the diffusible, is hable to variation in such circumstances as parathyroidectomy, or the administration of parathyroid extract

Of the diffusible calcium, probably 2 mgm. or so is in ionic form. It has been suggested that the remaining 4 mgm, may be combined with some substance of properties comparable, in this connexion, to those of citric acid. Quite probably, all three forms (if there be but three) are in equilibrium: variations in the amount of any one form must be reflected in variations in that of the others. It was, for example, pointed out that in prolonged diffusion experiments actually more than 60 per cent. of the total calcium passes into the diffusate, owing to the breaking up of the diffusible into the non-diffusible form.

Certain views 1 concerning the relationship of the parathyroids to calcium metabolism, implied rather than explicitly stated during the discussion, may be put into a fairly definite form

It has been clearly shown that injection of parathyroid hormone increases blood calcium without increasing absorption or diminishing excretion of the metal by the alimentary canal, since the typical rise can be obtained in anæsthetised, eviscerated animals. This rise must, therefore, occur at the expense of calcium either of the bones or of soft tissues,

 $^1$  A similar view has been expressed to the writer, independently, by Mr. Hoyle, of the Pharmacological Laboratory, Cambridge.

or of both. The hormone, in fact, must mobilise calcium from some reserve store. It appears that in certain cases of so-called 'renal infantilism'—a state in which nephritic changes accompany failure in body development—there occurs both a high level of blood phosphate, and a hypercalcæmia, associated with severe rachitic changes in the bones. A case was also described in which the bony changes known as 'osteitis fibrosa' were accompanied by a blood calcium level of 17 mgm. per cent., and the appearance of very definite adenomatous tumours of the parathyroids. It has been stated that young animals, fed on a calcium-poor diet, show definite parathyroid

hypertrophy.

Taken together, these observations seem strongly to suggest that, whatever the immediate source of the blood calcium, any prolonged rise in its amount results in the draining of the element from the bones. and that the action of the parathyroid hormone is in favour of such a transference A consideration of the relative amounts of calcium in the bones and the circulating fluid makes it obvious that only after a prolonged demand would any measurable effect be produced on the relatively enormous calcium store of the bones. It is well known that cardiac and nervous tissues are extremely sensitive to Ca /K balance, and it is difficult to imagine that any marked or prolonged rise in blood calcium would take place entirely at the expense of the soft tissues. Such data as are available suggest that calcium is concerned with the maintenance of cell surface structures, it is hard to picture such structures parting with calcium without the occurrence of marked disturbances.

The evidence concerning the point of action of vitamin D is, at present, meagre, and the subject still obscure. Some observations suggest that it promotes calcium absorption, possibly by some influence on the  $p{\rm H}$  of the intestinal tract. Obviously any agency tending to shift the reaction to, or to retain it at, the acid side of neutrality would favour the existence of soluble rather than insoluble calcium compounds. Such an explanation would, however, place the vitamin in the same category as a phosphaterich diet, which increases the rickets-producing power of a calcium-poor diet by hindering the absorption of the element. Evidence of the action of vitamin D on the mechanisms of bone formation, such as the phosphate esterase of Robison, is so far lacking.

Little light can at present be shed on the difficult question of the relationships of Ca" and Cl' ions, and of pH, in blood and tissues. It is suggested that the treatment of certain conditions, such as the cedema of nephritis, by calcium chloride depends as much on the readjustment of the Na /Cl' ratio as on any effect of calcium per se; it is well known that tetany is favoured by an increase, and tends to be relieved by a decrease of the alkali reserve, though Collip has shown that both in tetany and in hypercalcamia there is a terminal uncompensated acidosis.

### Congress of the History of Medicine.

THE sixth International Congress of the History of Medicine was held during the week July 18-23 under the presidency of Dr. J. G. de Lint, lecturer on the history of medicine in the University of Leyden. The meetings during the first three days were held at Leyden and the rest of the week at Amsterdam. The attendance was larger than at any previous congress organised by the International Society of the History of Medicine. No less than

twenty countries, among which Germany and Austria figured for the first time, were represented, so that the Congress, as many of the speakers remarked, was for the first time really international. Owing to the simultaneous annual meeting of the British Medical Association at Edinburgh, where a section of the history of medicine had been inaugurated, only a few British representatives, including Sir D'Arcy Power, Dr. Charles Singer, and Dr. J. D. Rolleston were present.

As on previous occasions, a great variety of subjects was discussed. Nearly ninety papers in all were presented to the Congress, but in the absence of their authors many had to be taken as read, and no speaker was allowed more than ten minutes for his communication. Anthropology was represented by papers by Dr. M. A. van Andel on folk medicine in myths and legends; by Prof A. W. Niewenhuis, on the views of primitive races on the sexual life of mankind, and by Dr V. Bugiel, on the personification of disease in Polish folklore. Classical antiquity was represented by papers on doctors and public opinion in ancient Rome, by Dr. R. Neveu; medical athletics in antiquity, by Prof. W. Haberling; ancient medicine and philosophy, by Dr. J. H. Lulofs; and terra cotta statuettes illustrating diseases from the Graeco-Roman museum at Alexandria, by Dr Angelica Panayotatou. Papers on medieval medicine included communications by Prof. Karl Sudhoff on medicine m the twelfth and thirteenth centuries; by Dr A. C. Klebs on a Catalan plague tract of April 1348, by Prof. P. Capparoni on a manuscript from the school of Salerno and an Italian translation of the thirteenth century of the "Thesaurus Pauperum, by Petrus Hispanus; by Prof. H. E. Sigerist, on St Sebastian; and by Dr. J. D. Rolleston, on St. Blase. Contributions to the history of anatomy consisted of papers on the development of anatomy in Spain shortly after Vesalius, by Dr. F Lejeune; Van Calcar's original drawing for the title-page of Vesalius's Fabrica, by Dr. Le Roy Crummer; and an unknown portrait of Vesalius, by Dr. F. M. G. de Feyfer.

Several communications dealt with the history of pharmacology, such as Johannes Mathaeus Faber's work on belladonna, by Dr. F. B. Kilmer, the origin of druggists' shops, by Dr. A. Schmidt; the deontology of the druggist in past ages, by Dr. O. van Schoor; and the title-pages of some old herbals and pharmacoporas published in Holland, by

Dr. H. Cohen

As was to be expected, many papers were devoted to Boerhaave, such as Boerhaave's prescriptions for some English patients, by Mr. C. J. S. Thompson, Boerhaave in Italy, by Prof. A. Castigliom: Boerhaave's letters to J. B. Barraud, by Dr. E. Darmstaedter; and La Mettrie's translation of Boerhaave's Aphorisms, by Drs. Laignel Lavastine and J. Vinchon Homage was also paid to Boerhaave's memory by a visit immediately after the opening ceremony to his tomb in the Peterskerk, by the inauguration of a memorial tablet in the house in which he died, and by the decoration of his statue with a wreath, on which occasion Dr. W. H. Welch, professor of the history of medicine at Johns Hopkins University, delivered an encomium on this great Dutch physician and clinical teacher.

Other papers relating to Dutch medicine apart from those on Boerhaave were Holland's contribution to clinical thermometry, by Dr. E. Ebstein; the first professor at the University of Leyden, by Dr. J. E. Kroon; Dutch hospitals as seen by a Frenchman, by M. Fosseyeux; and the history of spectacles in the

Netherlands, by Dr. H. Weve

The executive committee spared no pains to make the Congress a success by the arrangement of receptions, exhibitions, visits to places of interest, and the delivery of special addresses. Receptions were given by the Burgomasters of Leyden and Amsterdam, by the Minister of Public Instruction and Fine Arts at The Hague, by Mr. and Madame Fokker at Boerhaave's house, and by the Burgomaster of Enkhuisen during a trip on the Zuyder Zee, which included a visit to the picturesque inhabitants of Volendam.

Drs. B. W. T. Nuyens, F. M. G de Feyfer, J. van du Hoeven, and A. J. Lamers arranged a remarkable collection in the Municipal Museum at Amsterdam consisting of pictures by Rembrandt, Jan Steen, Teniers, and other works from various Dutch galleries, sculpture, books and incunabula illustrating the history of medicine. An interesting exhibition of instruments made by famous Dutch physicists in the seventeenth, eighteenth, and commencement of the nineteenth centuries was held at the physical laboratory of the University of Leyden, where Dr. C. A. Crommelin, the assistant director, gave an address illustrated by portraits of Huyghens, the Musschenbrocks, and other contemporary Dutch scientific workers. The same evening addresses illustrated by kmematograph films were given by Drs. A. Scherbeck and W. H van Seters on the work of Leeuwenhoek and Swammerdam Lectures were also given on the history of the treatment of nervous and mental diseases, by Dr C O. Ariens Kappers; the doctor in caricature, by Mr. C Veeth; and the bier of the surgeons and druggists preserved in the church at Wokkum, by Dr J B F van Gils.

The proceedings terminated with a banquet, when the speakers consisted of the president of the Congress, the president of the Society, Dr Tricot-Royer of Antwerp, the president-elect of the next Congress, Prof. Pietro Capparoni, and Dr. J. D. Rolleston, chosen by lot to propose the health of the ladies.

The next Congress will be hold at Rome in 1930, but the International Society of the History of Medicine will form a section in the Congress of the History of Science to be held next year at Oslo

### University and Educational Intelligence.

An institute for research in medicine is to be founded at Heidelberg. According to the Chemiker-Zeitung, the building will be creeted near the projected thermal bath and will contain special departments for research in pathological physiology, serum investigation, etc., and for the study of physics and chemistry as applied to medicine.

The Albert Agricultural College, Glasnevin, Dublin, which has been engaged in agricultural teaching and research since 1851, has recently been reorganised so as to accommodate the enlarged Agricultural Faculty of University College, Dublin (National University of Ireland), and will henceforth be under University control. The following appointments have been made: Director and professor of agriculture, Prof. J. P. Drew; professor of plant pathology, Dr. P. A. Murphy; lecturer in animal nutrition, Mr. E. J. Sheehy; lecturer in agricultural chemistry, Mr. Geo. Stephenson; lecturer in agricultural botany and bacteriology, Mr. M. J. Gorman; lecturer in plant breeding, Mr. M. Caffrey; lecturer in horticulture, Mr. G. O. Sherrard.

The British Institute of Philosophical Studies has arranged courses of lectures for the Michaelmas term by Prof. S. Alexander on "Value" (Truth, Goodness, Beauty); Mr. John Hobson on "Economics in relation to Ethics"; Prof. Leonard Russell on "The Approach to Philosophy"; Mr. Sydney E. Hooper on "Introduction to Philosophy", and Dr. William Brown on "Psychology". In the Lent term the Hon. Bertrand Russell will lecture on "The Philosophy of Physics," and Dr. Morris Ginsberg on "Social Psychology". In the Summer term Prof. Clement C. J. Webb will give a course of four lectures on "The Philosophy of Religion," and Prof. C. Lloyd Morgan a course of six lectures on "Mind in Nature". A full syllabus can

be obtained on application to the Director of Studies, 88 Kingsway, London, W C 2.

THE tutorial system of Oxford and Cambridge has, for many years, been well known in academic circles in the United States, its merits having been canvassed by returned Rhodes scholars and others, and somewhat sımılar systems having been introduced in Harvard and other American universities. The Harvard system is described in the January and April numbers of *The Educational Record*. Its main features are: each student at the end of the first year of his four-years' course is assigned to a tutor, who becomes thenceforth his adviser in all his studies, the tutors, at first chiefly young men, are now holding positions of all grades, from assistant to full professor; at least half of them combine tutoring with course lecturing; the number of pupils to a tutor who devotes his whole time to tutoring varies from 25 to 45. Conferences between tutor and pupil. commonly lasting an hour, take place once a week or fortnight in the second year, and once a week in the third and fourth, normally the students meet their tutors singly; the conferences are not in the nature of private lectures, most of the talking being done by the student, and have as little as possible to do with the ground covered in the courses taken; attendance by the student is entirely optional. The objects of the system are thus summed up: to devote more attention to the undergraduate as an individual, to treat him as a whole being (not, as under the American 'credit' system, as a conglomeration of intellectual fragments), to make him more largely educate himself, and to provoke in him an interest in so doing. It has increased the annual college teaching costs by about 45 dollars for each student.

EDUCATION in Finland is dealt with in a series of articles written by various authors for "Finland, the Country, its People and Institutions" (Otava Publishing Company, Helsinki, 1927), and issued as a separate pamphlet of fifty pages. This symposium, well printed in excellent English, and illustrated, comprises chapters on the elementary school system, secondary education, adult education, athletics, seats of learning, and the technical university. To the student of school systems the history of education in Finland is interesting, especially on account of the extraordinarily important place assigned to language teaching and the predominance in educational theory and practice of the influence of Uno Cygnaeus, the 'father of the elementary schools' Swedish, for centuries the official language of the country, Finnish, the mother-tongue of the bulk of the population, at least two of the great languages of the world, whether classical or modern, and, until recently, Russian, have all been included in the ordinary grammar school curriculum. The genius of Uno Cygnaeus, an enthusiastic follower of Pestalozzi, made a deep impression on his contemporaries and is to-day inspir-ing a movement towards a closer connexion with practical life, alike in elementary and secondary schools. Adult education is promoted by many agencies and is encouraged by State grants amounting, for the year 1926, to ten million marks. In 1920, Parliament decided to make the State directly responsible for the development of public libraries, and set up a libraries board, on which various educational organisations are represented, and a bureau, and divided the country into districts for propaganda and advisory work, with a library advisor in each. The principal seat of learning is the University of Helsinki (Helsingfors), a State institution. There are also two private universities, a commercial high-school, and a State technical university.

#### Calendar of Discovery and Invention.

September 18, 1883 — On Sept 1, 1883, W R. Brooks, at Phelps, NY., detected a comet which became an object of great interest owing to its identification with the Pons comet of 1812. This identity appears to have been first announced by the Rev. George M. Searle of New York in a letter published on Sept 18.

September 19, 1648—In Nov. 1647, a month after the death of Torricelli, Pascal suggested to his brother-in-law, Perier, the experiment of carrying a Torricellian tube up a mountain and noting the variation in the height of the mercury. It was not found possible to make the experiment until Sept. 19, 1648, when a party ascended the Puy de Dôme, near Clermont, equipped with a tube. At starting, the mercury stood at 26 in., but at the summit it had fallen to 23 in. "the party being greatly pleased at this, as indicating the relation between the height of the mercury and the height of the station."

September 20, 1849.—A patent of considerable interest in the early history of the applications of electricity is that of Staite and Petrie, E.P. 12,772, of Sept. 20, 1849. A method was devised to overcome the injury which the indium sustained when fused by a discharge between two carbon electrodes, and consisted in allowing the discharge to take place between an indium rod and the grains or powder of the indium it was desired to fuse

September 21, 1812.—On this date Count Francesco Zambeccari, accompanied by Vincenzo Bonaga, ascended near Bologna in a balloon of the Montgolfier type, heated by a lamp of the design of J. N. von Laicharding, an Innsbruck professor of natural history. The lamp burnt oil or spirit and was claimed to decrease the danger of fire to which the Montgolfier type of balloon was naturally subject. The wind blew the balloon against a tree, the branches of which upset the heating apparatus, the lamp exploded, the balloon crashed, and Zambeccari was killed.

September 22, 1859.—The publication of Rankine's work, "The Steam Engine," marks an epoch in the application of scientific principles to practical work. In his preface, dated Sept. 22, 1859, Rankine wrote: "The principles of thermodynamics, or the science of the mechanical action of heat, are explained in the third chapter of the third part more fully than should have been necessary but for the fact that this is the first systematic treatise on that science which has ever appeared, the only previous source of information regarding it being detached memoirs in the transactions of learned societies and in scientific journals"

September 23, 1846.—The planet Uranus, before its actual discovery by Sir William Herschel in 1781, had been observed as a fixed star on at least seventeen other occasions, beginning with Flamsteed in 1690. In the close study following its recognition as a planet, many irregularities were discovered which were outside the admissable limits of error. The investigations of Adams and Leverrier showed that no explanation of the motions of Uranus was admissible except that of a planet exterior to Uranus. It was at the Observatory of Berlin that the good fortune of discovering the new planet, Neptune, fell to the chief assistant, J. G. Galle, on Sept. 23, 1846.

September 24, 1852.—One of the earliest successful dirigibles was that of Henri Giffard, a Frenchman who, in 1852, invented a spindle-shaped gas-bag, propelled by a 3-h.p. steam engine. The ship was about 140 ft long and 40 ft. diameter, and contained 88,000 cubic feet of gas. The bag was enclosed in a net from which was suspended a spar 66 ft. long. The engine car hung from the spar. A short journey was made in the airship on Sept. 24, 1852, when a speed of about 3 miles an hour was attained.

#### Societies and Academies.

LONDON.

Institute of Metals (Derby, annual meeting), Sept. 6 -L. Aitchison · Metals in modern transport (Lecture). In general, the properties that lead to the greatest employment of the non-ferrous metals and alloys are (1) A high resistance to corrosion. (2) High values of thermal or electrical conductivity. (3) A low value of specific gravity. In addition, the properties of ease of machining, ease of cold working, and simplicity of casting contribute to the wider usefulness of the materials. A high resistance to corrosion is a conspicuous feature of nickel and its alloys; this property is of service in cupro-nickel condenser tubes. The alloys of copper are for this reason also used in condenser tubes and turbine blading, and gun metal and phosphor bronze castings. Metals having a much lower specific gravity than iron and steel and mechanical properties comparable with those of the ferrous metals are of great importance in transport systems. The alloys that are actually employed are those based upon aluminium and magnesium. The alloys of aluminium at the present time are much more extensively employed than the alloys of magnesium. A variety of aluminium casting alloys can be employed, and are more or less interchangeable, but the majority of the wrought parts are made in duralumin. used in rail coaches and food containers, in constructing panels and structural sections in tramcars, motor-cars, and motor buses, in automobile engines and in aircraft. Various kinds of non-ferrous metals having tin, or lead, or copper as their basis are used as antifriction materials.

Sept. 7.—Marie L V. Gayler: The under-cooling of some aluminum alloys. The effect of under-cooling on the macro- and microstructure of some siliconaluminium and copper-aluminium alloys has been studied. It was not possible to under-cool 'modified' silicon-aluminium alloys systematically; the curves of solubility represented by the 'modified' diagram correspond closely to the supersolubility curves of the 'normal' alloys.—A. R. Raper: The equilibrium diagram of copper-tin alloys containing from 10 to 25 atomic per cent. of tin. The alloys have been examined both by thermal and micrographic analysis. The  $\alpha + \beta - \beta$  boundary shows a sudden change in direction at 580°, which together with other micrographic evidence favours Stockdale's view of a polymorphic change of the  $\beta$  constituent. The eutectoid point is at tin 16·15 (or 73 15 per cent. copper by weight), the temperature of the inversion being 520°. The 'transformation' curve has been determined carefully by thermal analysis; the slight horizontal at about 610° exists from tin 22.5 to tin 25 at a temperature of 638°. Evidence for a new eutectoid at tin 23 has been obtained .- F. Hargreaves: Effect of work and annealing on the lead-tin eutectic. A marked softening action of work at air temperature on the lead-tin eutectic is found. In the case of 78 per cent. reduction in thickness, the Brinell hardness is reduced from about 14 in the chill-cast condition to  $4\cdot 2$  when tested immediately after hammering. This value is actually lower than that of either constituent in the pure state -W. Hume-Rothery: Researches on intermetallic compounds (vi.). The reaction between solid magnesium and liquid tin. The reaction has been studied between 250° C. and 350° C. When a rod of magnesium is stood in a limited quantity of molten tin, the magnesium dissolves until the liquid reaches the equilibrium composition at the particular temperature concerned. Since, however, true equilibrium requires

the compound Mg<sub>2</sub>Sn (probably Mg<sub>4</sub>Sn<sub>2</sub>) as the phase in equilibrium with the liquid, a further reaction of the type, solid magnesium +liquid=solid magnesium stan-nide, tends to take place When sufficient magnesium has dissolved to give the liquid the equilibrium composition, all further direct reaction is stopped by a thin film of magnesium stannide which shows no appreciable thickening even after three weeks at the above temperatures. On the other hand, a few large crystals of magnesium stannide are sometimes formed by a slow reaction. This is probably the ordinary phenomenon of crystal growth due to surface energy effects, since the thin surface film has a high surface energy and so tends to form a more compact mass. But any solution at one point exposes more magnesium to the action of the liquid, and so the reaction gradually proceeds—W. T. Cook and W. R. D. Jones: The copper-magnesium alloys (Part 2). The ductility of these alloys depends primarily on the forging temperature If this temperature be low, the elongation and the reduction of area are impaired seriously, and the values are not restored by subsequent heat-treatment. The mechanical properties of copper-magnesium alloys containing up to 11 per cent. copper are not improved by simple heat-treatment, which causes a general decrease in test values. The addition of copper to magnesium up to about 2 per cent. is beneficial. Beyond this amount the increase in tenacity is small, whilst there is a regular decrease in ductility and a proportional increase in specific gravity. There is no advantage in adding more than this amount of copper to magnesium either for castings or for forgings.

Sept. 8.—C. J. Smithells, W. R. Pitkin, and J. W. Grain growth in compressed metal powder. The changes which take place in certain properties of bars of pressed tungsten powder when the temperature is gradually raised have been investigated. These changes are attributed to gram growth, which begins at a temperature determined by the particle size of the powder and the pressure used in forming the bar. Using powders with mean particle size 0.6-3.5µ, and pressures 8-32 tons/sq. in., the temperature at which grain growth could first be detected varied from 1100° K. to 1500° K— C. H. M. Jenkins: The constitution and physical properties of some of the alloys of copper, zinc, and cadmium. The general results indicate that the use of cadmium-bearing zinc does not produce any marked alteration in the physical properties of the brass. Additions of cadmium up to 1 per cent. by weight cause an improvement in the tensile strength, generally accompanied by a reduction in elongation. The effect is most noticeable in the cast 70:30 brass, and is less pronounced in worked material —H. Sutton and A. J. Sidery: The protection of aluminium and its alloys against corrosion. The resistance of aluminium, duralumin, and of certain other aluminium alloys to corrosion by sea-water is considerably increased by anodic oxidation and the subsequent application of a grease, such as lanoline. Electro-deposited coatings of zmc, 0.005 m. thick, afforded better protection to aluminium than did coatings of cadmium of similar thickness, but the two types of deposit appeared to give an approximately equal protection when applied to alloys of aluminium. Unsatisfactory results were obtained from nickel deposits of normal thickness.

—H. Sutton and J. W. W. Willstrop: The nature of the film produced by anodic oxidation of aluminium. The metallic aluminium is volatilised in dry hydrogen chloride. The films isolated from treated commercial aluminium sheet are usually of a grey colour, due to traces of carbon left behind when the aluminium sublimes as chloride, and they contain elementary

silicon. Films varying in thickness from  $0.033\mu$  to  $2\mu$  have been obtained, the thickness of the film produced by the usual standard treatment being about  $1\mu$ . From the volume of gas evolved by treated aluminium when heated in vacuo to 1200° C., the film is shown to consist of oxide and not of hydroxide.— W. Hume-Rothery and S. W. Rowell: The system magnesium-cadmium. The equilibrium diagram of the system magnesium-cadmium has been investigated by thermal and microscopic methods. The system contains a solid solution based on cadmium and denoted  $\alpha$ , a definite intermetallic compound MgCd<sub>2</sub>, and a solid solution in magnesium denoted  $\beta$ . The solid solution a extends from 0 to about 24 atomic per cent. magnesium at most temperatures. The compound MgCd, does not form any solid solutions, whilst the  $\beta$  solid solution extends from about 40 to 100 atomic per cent. magnesium The  $\beta$  solid solution undergoes a transformation at temperatures about 200° to 250° C., but the maximum temperature of this change is at 54 atomic per cent. The change seems to be of the same nature as that of the  $\beta$  brasses Prolonged annealing is necessary to attain equilibrium m the solid alloys in the neighbourhood of the compound MgCd2.—Cyrıl S. Smith: Note on cathodic disintegration as a method of etching specimens for metallography. Silver-copper alloys are particularly suited for etching by this process, which causes stainmg of the copper-rich constituent as well as removal of the silver.

#### PARIS.

Academy of Sciences, Aug. 17.—Akımoff. Fourier-Bessel transcendentals with several variables.—F Gonseth and G Juvet The metric in space of 5  $\,$ dimensions of electromagnetism and of gravitation.

—B. Cabrera and A Dupérier: The paramagnetism of the palladium and platinum families.—A. Duboin: The application to the oxides of iron and neodymium of a general method of synthesis of silicates.—Georges Lumet and Henri Marcelet: The utilisation of marine animal oils and fish oils in motors. These oils have been used to work a Diesel-Hindl motor without special adjustment. The power of the motor was practically unchanged when the fish oils were sub-stituted for gas oil. Corresponding with the lower calorific value, more fish oil than gas oil was required. The only difficulty was caused by the higher viscosity of the fish oils, and this was overcome by a preliminary heating.—J. Dadlez: The proportion of nitrous fumes in the neighbourhood of an arc lamp used for medical treatment. Under normal conditions the amount of oxides of nitrogen produced are without danger, but in a small room efficient ventilation must be provided.

Aug. 22.—A. Lacroix: The lithological constitution of the volcances of the central southern Pacific. The volcance islands in the southern Pacific Ocean can be grouped under three lithological series, nephelimic, intermediary, and without nepheline. The strict classification of eruptive rocks into a Pacific type and an Atlantic type cannot be maintained in this form.—Riquier: The numerical resolution of certain systems of integral algebraical equations with any number of unknowns.—C. Sauvageau: The continuous growth of certain annual Pheosporese—Charles Nicolle and Charles Anderson: The experimental transmission of the spirochete of Spanish recurrent fever by Ornithodorus moubata and the mechanism of this transmission. O. moubata is capable of transmitting not only the Dutton spirochete of which it is the natural transmitter, but also two others, one of which is allied to the Dutton spirochete, the other quite different. The mechanism

of transmission in these cases is the same, it is a natural transmission—Georges J. Remoundos Anew generalisation of the Picard theorem—Léon Pomey: The existence of non-linear differential and integral equations (with any number of variables) of which solutions exist in the same domain as the coefficients (normal non-linear equations).—J. A. Lappo-Danilevski. The algorithmic resolution of the problem of Poincaré concerning the construction of a monodrome group of a given system of linear differential equations—Miron Nicolesco: Bipoint functions and conjugated areolairely functions —René Lagrange: Certain suites of polynomials — De Fleury: The forms of the combustion chambers in internal combustion motors and their effect on endurance. The best practical constructive solutions of the problem tend towards very high compressions, with explosion chambers possessing a high ratio of surface to volume for combustibles such as petrol liable to develop an explosive wave.—F. Gonseth and G. Juvet: Schrodinger's equation —W. Kopaczewski and M. Rosnowski. Electrocapillary phenomena and the ions —Tr. Negresco: The quantitative sensibility of the lines of the spectrum. The sensibility of any given line in the spectrum, in a given source of emission, depends uniquely on its intensity in the spectrum of the pure metal obtained under identical conditions.—Henri Marcelet: The determination of some physical constants of marine animal oils. The data given for thirty different oils include the heat of combustion, flash point, specific gravity, and viscosity.—A. P. Rollet: The behaviour of various metals in the electrolysis of water by the alternating current.-Mme. N. Demassieux: The action of oxalic acid upon some soluble salts of lead .-- W. Ipatieff and W. Niklaeff. The action of hydrogen upon tin salts at high temperatures and pressures. At 300° C., with hydrogen under 38 atmospheres pressure, hydrated tin oxide is reduced to the stannous state; at 350° C. and 50 atmospheres, the reduction goes further to metallic tm. Stannic sulphate  $(302^{\circ}$  C. and 50 atmospheres) gives stannous sulphate in solution and crystals of stannous sulphide.—L. Hackspill and E. Rinck: The reciprocal displacement of sodium and potassium from their chlorides. An experimental study of the reaction KCl+Na=NaCl+K.—André Léauté: The low temperature distillation of long flame coals agglomerated by tar or a tar oil. The experiments described were directed towards the determination of the best proportion of oil or tar giving a hard solid residue.—Pereira de Sousa. A new deposit of intrusive rocks containing sodium in Portugal.—J. Lacoste: The experimental determination of the dynamic magnification of seismographs with platform.—L. Petitjean: A periodicity and symmetry of the rainfall curve at Algiers Application to the prediction of dry and rainy periods in Algeria.—Cam. De Bruyne: Contribution to the study of the nutritive process of the oosphere of the Abietineæ.— H. Colin and A. Augem: The nature and metabolism of the glucides in the Iris—F. Viés and A. de Coulon: The interpretation of the curves of the receptivity index of mice for grafts of tumours.—S. Voronoff: The results of the grafts on the flock of sheep of the Gouvernement général d'Algérie.

#### SYDNEY.

Linnean Society of New South Wales, July 27.—H. J. Carter: Australian Coleoptera: notes and new species (No 5).—G. H. Cunningham: The Gasteromycetes of Australasia (9): Keys to the genera and species of the Lycoperdaceæ. The ontogenetic position of each of the genera is discussed and an artificial key based on structural similarities and differences is

proposed.-J. R. Malloch: Notes on Australian Diptera (No 11). A full account is given of the Australian Calliphoridæ, and the family is divided into Calliphorinæ, Metopiinæ, Sarcophaginæ, Chrysomyiinæ, and Rhinunæ.—A. M. Lea · Descriptions of new species of Australian Coleoptera (Part 19). Two new genera and 38 new species of beetles of the family Curculionide, mostly from Queensland, are described—

J. McLuckie and A. H. K. Petrie. The vegetation of the Kosciusko Plateau (Part 1) The plant communities. Three zones are recognised: alpine, subalpine, and montane. The three great types of communities are (a) Eucalyptus forest, represented by the E corracea, E. Gunnii, and E. stellulata consociations; (b) grassland represented by the Poa consociation and the Poa-Celmisia association; (c) the marsh vegetation The factors controlling the timber line and the interrelations of the communities of the marsh vegetation are also discussed

#### Imperial Mineral Oil Resources.

DISTINGUISHING, if not the chief, merit of a periodic congress is the opportunity afforded for taking stock and gauging progress of development, particularly when the terms of reference connote applied science. Even if deliberations produce nothing startlingly new, as is often the case, the inevitable correlation of independent lines of reasoning and research serves as a stimulant to the delegate mind and creates a wider perspective, at the same time tightening the grip on essentials. This in turn has its natural repercussion amongst the greater body of workers, and thus is the spirit of technology constantly enlivened.

Petroleum is a case in point. Its consideration at the second (triennial) Empire Mining and Metallurgical Congress, judged from the papers now available, is largely recapitulatory, but there is clearly apparent the aim at such co-ordination of data as may lead to some solution of the thorny problem of Imperial mineral oil resources and future supplies. The setting for such a discussion, Canada, is singularly appropriate, though paradoxical while it emphasises the truly Imperial aspect of the question, it throws into sharp relief the unfavourable position of that great Dominion, the contribution of which is less than 0.02 per cent. of the world's petroleum production; like Great Britain, Canada is dependent on foreign sources of supply for her needs.

The problem resolves itself into a dispassionate survey of hard facts: the maximum quantity of petroleum won from truly Empire sources lies between two and three million tons per annum, these limits constitute a reasonable estimate for the future. On the other hand, the total consumption of petroleum products in the Empire amounts to between ten and eleven million tons per annum, and is likely to increase considerably with each successive year. Thus Empire resources are hopelessly inadequate even for present needs. There follows the natural question: What exactly are our Imperial petroleum resources, both actual and potential, and to what extent is the British Empire committed to foreign oil supplies in the future? Failing a satisfactory solution in the shape of technical guarantees, what is the alternative to the existing situation?

In substance these questions are not new; they have been raised a hundred times both on the platform and in print; they have been answered in diverse ways, but always with strong individual bias. The optimistic predictions of undeveloped

oil-pools, shale-oil prospects, coal and liquid fuel substitutes, and similar panaceas variously prescribed to meet ultimate contingencies, are well known. In the light of present knowledge, such unbounded optimism is premature. At the moment the circle of argument, like that of the origin of petroleum, is still intensely vicious, but there are signs that this second Congress may be destined at last to break it.

To clear the ground, a distinction must be drawn between truly Imperial oil resources and those, though developed by Imperial interests, situated in extra-Imperial territory; this is a point usually overlooked, but it is all-important to the present issue. Thus in the first category are placed India (with Burma and Assam), Trinidad, Sarawak, Egypt, and Canada, expansion is probable in the first three, extremely doubtful in the two remaining countries; to the same list may be added potential resources of New Guinea and North Borneo. Much is heard of the untapped oil reserves of the main continent of Africa, also Australia and New Zealand; unfortunately, the wish fathers the thought. Technically, the evidence tends to discount the discovery in these lands of major oil-pools destined to weigh heavily in the scheme of things; the great red spaces on the map of the world which depict Imperial terrain, he, with one exception, tantalisingly outside the girdle of prolific oil production

Imperial petroleum interests in foreign countries are highly ramified and are of supreme economic and political import; they embrace Mexico, Persia, Venezuela, Peru, Argentine, Colombia, Rumania, and Galicia, among others. Russia is a problem unto itself, with oil as with politics; the march of time may determine the resumption of international competition for her undeveloped resources, with British interests reasserted, but prophecy concerning this unhappy country is dangerous. 'Iraq fascinates by its yet unproven possibilities, as also other regions of south-west Asia: Empire commitments here are much entangled with foreign policies, perhaps not disadvantageous in the long run. But the crucial point to remember is this: these countries constitute resources to the Empire only so long as political relationship is stable and international commerce is untrammelled by inimical legislation or actuality of war. Admittedly it is hard to imagine the extreme circumstance in which all these channels of supply would be blocked, especially in the light of experience gained during the War, but there is danger in the position as it stands, which would be intensified a hundred-fold

if, for any reason, American sources were made unavailable for Imperial markets

The predominating position of the United States in the economics of world-supply and consumption of petroleum products has been defined so often as to be common knowledge; further statement is therefore superfluous here. To-day the Empire's dependence on that country for oil is as great as ever, for increased consumption more than balances increased production from extra-American sources. So long as one country is responsible for more than 70 per cent (80 per cent if Mexico is included) of the total annual output of a vital commodity, so long must it be the keystone of the whole economic structure, national and foreign, on which the relevant industry is reared. The free distribution of American oil supplies to Empire markets can only be disturbed by two eventualities. curtailment of exports to conserve national resources, or declaration of war. The first is feasible, in fact ultimately probable; the second is unthinkable, at least to the present generation. In any event, the fact that Imperial resources are totally insufficient to meet present necessities, much less any possible emergency arising from diminished trans-Atlantic supplies, serves only too well to indicate the real state of affairs. Moreover, in no other part of the world is it possible to predict, with confidence based on all available knowledge, the existence of undiscovered petroliferous territory of the magnitude and persistence of that possessed by the United States; geological work all over the world, though the detail of remote regions may still be lacking, is at least sufficiently comprehensive to justify that assertion.

Thus hopes of independence of foreign sources of oil production vanish quickly when the situation is carefully examined. In the course of his address to the Congress, Sir Thomas Holland stated the case succinctly: "Under normal conditions we must depend on outside sources for a seriously large part of our petroleum products; " and again, "It is important to remember that in case of temporary isolation, even the Empire sources of crude oil may not be accessible. In any event, they would be quite insufficient even if they were available to the full. . . ." It is quite impossible to encourage the slightest hope that the consumption-factor of eleven million tons or more of petroleum products per annum within the Empire can ever be attained by the utilisation of indigenous supplies. Thus technical guarantees fail and we are thrown back on alternative remedies.

Sir Thomas Holland invited the Congress to consider six points which we may summarise as follows: (1) Prospects of maintaining or extending Empire production of crude oil, (2) the extent to which oil-shale exploitation may supplement mineral oil supplies, (3) prospects of obtaining oil from low temperature carbonisation, (4) possibilities of oil substitutes obtained by processes similar to hydrogenation of coal, (5) prospects of alternative liquid fuel, e.g. alcohol, and (6) increased production of light oils by cracking processes, etc

The value of these headings lies in the fact that, as set out, they take nothing for granted, they presuppose no immediate remedy to be applied the moment emergency arises; they sponsor no premature optimism. The merit of the discussion along such lines lies in getting at the root of the whole matter, it is tantamount to saying, "Let us get clear for the moment from mere experimental data, from small-scale ideas which have scarcely transgressed the academic border-line What are the large-scale possibilities of these alternatives? Which are, and which are not, of commercial application, from which a definite solution of the problem can alone spring ? " Prof. Nash's paper on "Possible Auxiliary Sources of Liquid Fuels" should do much to focus attention on the true perspective of this subject; he is impressed with the many technical difficulties to be overcome before substituted fuels can compete with petroleum products, especially at current prices.

The problem thus debated is bound to open out along the right lines. Economic policy and military security of the Empire demand some tangible solution to the fuel question in the near future. It is useless to leave things to chance, it is unworthy to allocate the task to posterity. The suggestion has been made that standing committees should be formed in each Dominion to watch commercial petroleum developments, to inspire technical activities, and to translate results in terms of Imperial requirements. Nothing should be allowed to hamper the fruition of any scheme to this end. Organised research, conceived and executed on a large scale, or at least with the view of commercial requirements, should receive all the backing from the governments concerned that it is possible to give; the need for this was proclaimed loudly at Wembley in 1924; it is clear that the second Congress has vigorously affirmed this demand; it is to be fervently hoped that its efforts will not be in vain. н. в м

#### Flame and Combustion.

Flame and Combustion in Gases. By Prof. William A Bone and Dr. Donald T. A. Townend. Pp. xvi + 548 + 30 plates. (London: Longmans, Green and Co, Ltd, 1927.) 32s. net.

THE world to-day simply lives upon explosions: it moves and has its very being, in the air and on the roads, upon and under the waters, through the agency of flame The publication of a book dealing comprehensively with a subject of such public importance, by a master-worker, is therefore most opportune. It is so well-written that it should rank as a 'best-seller' with Ludwig's "Napoleon" and gruesome "Jew Suss," being as readable and exciting as a "Greenmantle" or a Mason 'shocker': though unfortunately the situations opened up are usually left unsettled and mayhap, even when 'continued in our next,' will still remain problematical The plot, in fact, is seemingly one of fearful complexity and the detectives engaged in unravelling the story have been far from possessed of the logical training and mental agility needed to dissect out its many threads: still, that definite pathways are being cleared through the maze cannot be doubted.

The book is most happily dedicated, by the authors, to Prof. H. B. Dixon, of Manchester, whose school is responsible for the greater part of the English work which is described The issue he raised in 1880, while but a reader in Oxford, in showing that carbonic oxide was rendered incombustible even by moderate drying, underlies the whole narrative and remains unsettled to the It seems to be a Snark that cannot be caught—pursue it as we may and rouse it even with the high potentials the electrician of to-day has placed at our disposal, not merely with jam and judicious advice, this last being perhaps the least acceptable to its non-conformist nature. Carbonic oxide is the most elusive customer we have in chemistry.

Facing the title page, the authors most appropriately quote the passage from Carlyle's "Hero as Divinty," one of the most characteristic of his essays, ending with the words, "From us too no Chemistry, if it had not Stupidity to help it, would hide that Flame is a wonder. What is Flame?" They carefully withhold the answer but, reading between their lines, we can see fairly clearly what a wondrous amount of stupidity has been displayed in seeking one: in fact, a large part of the book is a veritable comedy of errors. A deal of sack with very little bread. A wealth of experimental skill

is displayed but backed by a parlous deficiency of acute theoretic dissection.

Our science and our music seem indeed to be in similar quandary and but muddle through. Concertos are not concerted. Players are not playing their parts in the orchestra with effect, because of the lack of common rehearsals and the absence of skilled conductors. Verily is chemistry, at present, nought but an empiric art. We cannot be too grateful, therefore, to the authors for having set forth the evidence so clearly. If not all, they have put most of their cards upon the table and thereby challenged us to play them it is for us to take as many tricks as we can and they must not squeal if we are found to hold the trumps: frankly, their hand is a rotten one, their theory worse than threadbare

The purpose of the book is a review of the principal inquiries into the phenomena of combustion, from the time of Robert Boyle onwards to the present day, more particularly those of the period dating from about 1880, when Mallard and Le Chatelier and Berthelot and Vielle, in France, began the study of explosive combustion and were followed, in England, by H. B. Dixon, Smithells, Lewes, Dugald Clerk, Bone and his pupils and others. As the principal landmark in the survey is Dixon's theatrical discovery, over which we are still disputing, the period may well be spoken of as the carbonic oxide period. Of the five sections into which the work is divided, the first is introductory and historical, a brief but interesting survey of the work done mainly before 1880; in this, of course, Davy's and Bunsen's primary contributions are specially considered. The subjects discussed in the remaining four sections are:

- II. The Initiation and Development of Flame and Detonation in Gaseous Explosions (chaps. viii. to xviii.).
- III. Gaseous Explosions in Closed Vessels (chaps. xix. to xxiii.).
- IV. The Mechanism of Gaseous Combustion (chaps. xxiv. to xxxiii.).
- V. Catalytic and Incandescent Surface Combustion (chaps. xxxiv. to xxxvi.).

The work is profusely illustrated and contains a number of very beautiful photographs, showing the propagation of explosive waves, reproduced from Prof. Bone's communications in the *Proceedings of the Royal Society*. For the first time, an opportunity is given of appreciating the inventive skill and ability of the workers of the school which he has so happily called into being at South Kensington.

No. 3021, Vol. 120]

If we are ever to acquire ment by securing theoretic command of the internal combustion engine, we must understand the so-called mechanism of combustion—hitherto, our treatment of the subject has been soulless. The authors deal with it at length but perfunctorily, particularly in discussing the combustion of carbonic oxide and of hydrocarbons. It is my fate to figure as the villain in the piece First, under carbonic oxide (p. 337), as follows

"H. E. Armstrong, who always contends that chemical interactions cannot occur between two perfectly pure substances but require an electrolyte to form a 'closed conducting circuit,' supposed that the presence of steam, which he regards as being rendered conducting by association with some traces of an electrolytic impurity, provides the necessary conditions for the passage of the current, the oxygen playing the part of depolariser, as follows:

"According to this view, the molecules of oxygen and a combustible gas are in all circumstances absolutely inert towards each other. Indeed, quite recently, Armstrong declared carbon monoxide to be 'per se an incombustible gas,' adding that 'an explanation may be found in the assumption that when a moist carbon monoxide mixture is sparked or fired some hydrone is decomposed and sufficient hydrogen set free to act in a depolarising circuit together with the oxide, as thus:

H HO...H O H
H HO...H O H
HOH
HOH
$$+ \cdot \cdot \cdot + \begin{bmatrix} HO & H \\ HO & HO \end{bmatrix} O : C \longrightarrow HOH$$

$$+ \cdot \cdot \cdot + \begin{bmatrix} HO & H \\ HO & HO \end{bmatrix} O : C$$

$$= HOH + HO \cdot O : C$$

$$= 2H_{0}O + CO_{0}.$$

"This is perhaps the most elaborate and extreme form which any chemical explanation has hitherto taken, although all of them involve the assumption that in the combustion of carbonic oxide steam is continuously decomposed and regenerated."

Again, under hydrocarbons:

"Another alternative, namely, that the initial stage of the oxidation of a hydrocarbon might conceivably involve the transient formation of an unstable 'oxygenated' molecule, which, according to circumstances, would decompose more or less rapidly under the influence of heat, giving rise to simpler 'intermediate' products, had been suggested by H. E. Armstrong but never explored experimentally For on p. 417 of a new edition of Miller's 'Organic Chemistry,' published in 1880,

he had visualised such oxidation processes as primarily involving 'hydroxylation.' In our next two chapters, we shall see how this idea ultimately furnished a solution of the problem."

The issue to-day, as the authors recognise, is whether water be *essential* to the process of combustion.

On this first count I am said to come out badly, because I have 'ignored' "that there are well established cases (cyanogen, carbon bisulphide) in which apparently [I like the caveat and take it as evidence of a latent, uneasy conscience in the writers] combustion does not depend upon the presence of moisture." Also, because "any chemical view postulating that carbonic oxide cannot be burnt in flames except by the intervention of steam, which is continually decomposed and regenerated in the process, is countered by the spectroscopic evidence." One might use Mantalini language about spectroscopic evidence. I will only say: it leaves me cold; mercury, for example, as is well known, may be present in relatively large amount in a vacuum tube and yet be neither seen nor heard in the spectrum of the discharge. Carbon bisulphide is probably one of the liquids that is impossibly difficult to dry. The cyanogen used may even have been Bone-dry but no proof has been given that it was free from hydrogen cyanide. Go to, friend Bone, your 'well-established cases' may well go hang.

> "Nay, an thou'lt mouth, I'll rant as well as thou."

You, in your turn, ignore the prime fact, that the heat of combustion of carbonic oxide is below that of hydrogen; also—as shown by Grove—that carbonic oxide cannot be substituted for hydrogen, in the gas cell. It cannot, therefore, be oxidised by steam.

These are two nasty little facts which rather spoil your speculation: it hasn't the ghost of a theory about it. Your Bone-dry gas, after all, was not yet dry. Drying is an equilibrium process: some moisture will have been left upon the surfaces enveloping the gases. A vast amount of 'punch' has to be put into the discharge to get it through and yet combustion is far from complete. What happens when and as the discharge gets through? Is it not almost certain that hydrogen, imprisoned in the platinum electrodes and also platinum motes, are extruded into the gas? The photographs show that the explosive wave only 'gets up steam' gradually. As combustion is set up less and less readily as drying proceeds, drying being never complete, is it logical to assume that

another second process comes into play towards the end rather than that that initially in operation is dying out? The efficiency of your supposedly 'dry' process is so low, moreover, that the idea is not worth even provisional protection. No Comptroller could or would pass such a claim to an invention.

"Tempted by extremes,
The soul is most secure:
Too vivid loveliness blinds with its beams
And eyes turned inwards perceive the lure."

"Who seeks the shadow to the substance sinneth."

The fact is, we have reached the limit to which experimental inquiry into such an issue can legitimately be carried. We need to sit down and calmly and logically worry out all consequences of the observations on record: to call a constructionholiday—even engage Lord Cecil to 'disarm' our laboratories for a time and force workers to put on thinking-caps. We are in danger of making a fetish of laboratory work—the more since literary men have assumed control of the funds devoted to inquiry. The experimenter is apt to think too much of himself—to suffer from Cephalitis enlargica. He puts in his thumb and pulling out a plum thinks that he has, therefore, the right to say: 'What a good boy am I.' More often than not, he is a bad boy: the plum is a poor thing, unripe and sour; such plums should never have been made into a pie. This is particularly true in the field of biological inquiry. To experiment usefully, the motive of the experiment must be first visualised and must be logically conceived: its purpose must be clear and it must be carried through and the results punctiliously recorded and judicially interpreted with logical precision. These several ingredients are rarely present and mixed in due proportion in the research pie, nor is sufficient experience and intelligence imported into the operations.

The true art of scientific inquiry is the outcome of genius and acquired only by the few: no attempt is made to teach it, in any considered way. We have to change all this, beginning in the schools. We shall do well to stay experimenting for a time and call in competent accountants—if there be such—to take stock for us and balance our books. We may then realise how ragged a state our business is in and how necessary it is to reorganise it. Our subject is very much in the condition of certain large firms that have recently lapsed into inefficiency through incompetent management. We shall certainly find that much of our stock is worthless and need to scrap a lot. We shall be in a position to say what new stock is

most needed. What is good of that we have will make a brave show, when displayed apart from the rubbish with which it is now mixed. The book under notice shows this but also a lot of tares mixed with the wheat. Let us frankly admit that much of the work that is attempted to-day is too difficult for those who undertake it:

"For, although common Snarks do no manner of harm, Yet I feel it my duty to say, Some are Boojums——"

Passing to the second count, on which I win, as the authors magnanimously admit, I have a bone to pick with them on the ground of historical accuracy: I am an older sinner than they suggest. If they will turn to the first edition of my "Organic Chemistry" (Longmans), published in 1874, they will find on p. 216, under Aldehydes, a statement that these are probably formed from alcohols as the result of two distinct changes, the first being "the production of a compound of the form R'. CH(OH)(OH), which is subsequently broken

R'. CH(OH)(OH), which is subsequently broken up into the aldehyde and water, the former of these changes being brought about either (a) by the direct addition of oxygen to the alcohol or (b) by the combined influence of the nascent oxygen and water or (c) perhaps by the agency of hydroxyl (hydric peroxide  $(OH)_2$ ) itself, thus:

$$\begin{array}{lll} (a) & R' \cdot \operatorname{CH}_2(\operatorname{OH}) + \operatorname{O} & = R' \cdot \operatorname{CH}(\operatorname{OH})_2 \\ (b) & R' \cdot \operatorname{CH}_2(\operatorname{OH}) + \operatorname{O} + \operatorname{OH}_2 = R' \cdot \operatorname{CH}(\operatorname{OH})_2 + \operatorname{OH}_2 \\ (c) & R' \cdot \operatorname{CH}_2(\operatorname{OH}) + (\operatorname{OH})_2 & = R' \cdot \operatorname{CH}(\operatorname{OH})_2 + \operatorname{OH}_2 \\ & R' \cdot \operatorname{CH}(\operatorname{OH})_2 = R' \cdot \operatorname{COH} + \operatorname{OH}_2. \end{array}$$

I applied the 'hydroxylation' explanation throughout the rest of the book and, afterwards, in rewriting Miller's "Organic Chemistry," published in 1880. I may add that I began the study of flame in March 1867, when I first attended a course at the Royal Institution and heard Frankland's lectures on coal gas, in which he disputed Davy's explanation of the luminosity of flames.

The "never explored experimentally" in the quotation before given has an ungenerous twang. In framing my doctrine, I had before me the whole of the evidence bearing upon the 'hydroxylation' process accumulated up to that time: it was considerable. The work done by Prof. Bone and his fellow workers is of value and importance, as showing the character and course of the changes under these or those particular conditions: not as special evidence of 'hydroxylation.' Drugman's observation, a most important one, that ethylic alcohol may be obtained directly from ethane with the aid of ozone, is the only direct demonstration to be derived from the inquiry, in justification of the view I have long held and advocated, that

oxidation, in the first instance, invariably involves hydroxylation

The intensity of my behef is due to the firmness with which I hold the faith, that every chemical interaction is electrolytic in its origin and in its course and that the interactions in the Grove gas cell are to be taken as prototypical of all combustions. They are summarised in the expression:

The authors have yet to learn that "faint love never won fair lady." They are not 'real sports.' If they were they would not hedge by saying of the "hydroxylation theory, advanced more than twenty years ago" (sic, 1880–1927 = 47, alternatively 1874–1927 = 53):

"It should, however, not be interpreted or applied too rigidly, because doubtless in the long run the steady accumulation of new facts will necessitate some modifications and it would be unphilosophical to regard it as more than a serviceable tool for accomplishing further advances. It certainly affords what we believe to be a true explanation of slow combustion."

The authors have their doubts as to its application to flame. The fact is, they have not yet learnt how to apply it. Their oxidation schemes are but skeleton forms—the intimate process is not considered. They visualise thermal changes as intermediate operations. Formaldehyde is figured as just breaking down into hydrogen and carbonic oxide:  $CH_2O = CO + H_2$ . My sheet anchor has always been the belief in the superior charm first exercised by the oxygen atom and I would picture the downfall of formaldehydrol as a complex process, involving both hydroxylation and hydrolysis, at least in part often ending as shown schematically by the expression.

$$\begin{aligned} \mathbf{H}_2 \mathbf{C}(\mathbf{OH})_2 + 2(\mathbf{OH}) &= \mathbf{H} \mathbf{H} \mathbf{C}(\mathbf{OH})(\mathbf{OH}) \\ \mathbf{OH} \\ &= 2 \mathbf{H}_2 \mathbf{O} + [\mathbf{C}(\mathbf{OH})_2 = \mathbf{CO} + \mathbf{OH}_2)]. \end{aligned}$$

Carbonic oxide, in like manner, is the product of the hydrolysis of chloroform by caustic soda. If the CH<sub>2</sub> hydrogen were displaced by hydroxyl, formic and carbonic acids would be the products. In this instance, in my opinion, the hydrogen is quietly 'pulled away' by hydroxyl. The production of carbon from acetylene as well as that of hydrogen from formaldehyde, are also complex, not 'purely thermal' effects, I am satisfied.

At the close of 1891, the late Sir George Stokes

did me the honour to criticise an address of mine to the Junior Engineering Society. We discussed together the interactions occurring in flames. One of my points was that purely thermal changes were unlikely to occur. My attitude was then as conservative as my ignorance was great but all that has happened in the interval of thirty-five years justifies the final plea in my letter (Chemical Society's Proceedings, 1892, 22-27).

'Regarding the interactions in flames as consisting in a series of simultaneous and consecutive explosions, of which we can only examine the final steady state, it seems to me that the phenomena are necessarily of an excessively complex character and that their appreciation and successful interpretation must tax our powers of mental analysis in a very high degree. It will certainly be unwise at present to infer that the oxidation of the hydrocarbons or the separation of carbon and also of hydrogen from them, takes place entirely in any one way.'

The number of successive interactions involved in an oil engine explosion is almost incalculable, yet there can be little doubt as to their general course. It is impossible here, however, to discuss the subject at the length that would be necessary. The one point I desire to make is, that we not only need accurate experiment but also acute criticism of the results—what we get is worthy only of the nursery, not of the Senate House.

The book under review will have failed in its mission if it have not as result a searching examination of its many propositions.

HENRY E. ARMSTRONG.

### Science and Religion.

- Evolution in Science and Religion. By Robert Andrews Millikan. (Published on the Dwight Harrington Terry Foundation.) Pp. v + 95.
   (New Haven, Conn.: Yale University Press; London. Oxford University Press, 1927.)
   4s 6d. net.
- (2) Science and Human Progress. (Halley Stewart Lectures, 1926.) By Sir Ohver Lodge Pp. 187. (London: George Allen and Unwin, Ltd., 1927.) 4s. 6d net.
- 1) BOOKS about the relation between science and religion are apt to be heavy, but this reproach certainly cannot be levelled against Prof. Millikan's little volume. He gives in a few brilliant pages a sketch of the remarkable change which has come over the modern physical interpretation of the universe. He has been well placed to observe this change, having been, as he tells us, in direct touch with the older masters of the classical physics and

having watched step by step and participated in the revolution which was initiated by Rontgen's discovery of the X-rays. He attended Rontgen's first demonstration on Christmas Eve, 1895 · "As I listened and as the world listened, we all began to see that the nineteenth century physicists had taken themselves a little too seriously, that we had not come quite as near sounding the depths of the universe, even in the matter of fundamental physical principles, as we thought we had " (p. 10).

This gives the key-note of Prof Millikan's book, and most of it is a commentary, well documented, on the dangers of dogmatism both in science and in religion. His remarks about the shortcomings of the classical materialistic conception of the universe are amazingly frank "We can still look," he writes, "with a sense of wonder and mystery and reverence upon the fundamental elements of the physical world as they have been partially revealed to us in this century The childish mechanical conceptions of the nineteenth century are now grotesquely inadequate" (p. 27). Prof Millikan has all the enthusiasm of the experimentalist, looking to the continued advance of experimental science for the future progress of humanity. He has a firm belief in progress as "the most sublime, the most stimulating conception that has ever entered human thought"; one respects the belief and its stimulating power, even though it may be, as he admits, an illusion, but one cannot help thinking that if progress be merely "the increasing control over environment," something else is required to make human life fuller, more adequate, and happier.

Prof. Millikan's third lecture on "The Evolution of Religion" is scarcely so good as the other two—those entitled "The Evolution of Twentieth-century Physics" and "New Truth and Old"—but English readers will note with interest his view of the Scopes trial. While recognising the menace to freedom of thought implied in fundamentalism, he is inclined to think that the Scopes trial has done more good than harm, by ventilating the problems and making people think.

With Prof. Millikan's conclusions, as summarised in the following passage, few, we imagine, will disagree.

"Physics," he writes, "has at the present moment something to teach to both philosophy and religion, namely, the lesson of not taking itself too seriously, not imagining that the human mind yet understands, or has made more than the barest beginning toward understanding the universe. To-day physics is much more open-minded, much less dogmatic, much less disposed to make all-

inclusive generalisations, and to imagine that it is dealing with ultimate verities, than it was twentyfive years ago. This generalising farther than the observed facts warrant, this tendency to assume that our finite minds have at any time attained to a complete understanding even of the basis of the physical universe, this sort of blunder has been made over and over again in all periods of the world's history and in all domains of thought. It has been the chief sin of philosophy, the gravest error of religion, and the worst stupidity of science -this assumption of unpossessed knowledge, this dogmatic assertiveness, sometimes positive, sometimes negative, about matters concerning which we have no knowledge. . . . If there is anything that is calculated to impart an attitude of humility, to keep one receptive of new truth and conscious of the limitations of our understanding, it is a bit of familiarity with the growth of modern physics '

(2) The same lesson is taught by Sir Oliver Lodge in his Halley Stewart lectures. He also emphasises the great significance for all branches of thought of the revolution in physical concepts which the "younger heretics" enthusiastically support. Everything has been put into the melting-pot, and the creed of science is being reconstituted. With it all. Sir Oliver pleads for a return to simplicity in matters of everyday conduct and experience, to the common-sense view of life, in accepting which the wayfaring man, though a fool, does not err. His lectures, which cover a wide field of practical philosophy, are, we need scarcely say, distinguished by that genius for simplicity of exposition which make them so understandable of, and so useful to, the man in the street. He emphasises, as does Millikan, the danger of dogmatism in any form and the need for freedom and fluidity of belief.

Ultimate philosophy is to some extent a matter of personal conviction and experience; for this reason we do not propose to comment upon Srr Oliver Lodge's acutely dualistic scheme of things further than to express the contrary opinion that a more satisfactory philosophy is contained in the 'organic' view of reality put forward with such skill by Prof. Whitehead.

E. S. R.

## The Soil and Civilisation.

Soil and Civilisation: a Modern Concept of the Soil and the Historical Development of Agriculture. By Milton Whitney. (Library of Modern Sciences.) Pp. x+278+5 plates. (London: Chapman and Hall, Ltd., 1926.) 15s. net.

THE concept that the author sets out to develop is that "the soil is not the dead, inert, and simple thing often referred to as 'dirt.' It is No. 3021, Vol. 1201

essentially a factory where raw materials are converted into finished products" In other words, the soil must now be regarded as dynamic rather than static, as indeed a living thing having complicated functional activities that react on one another and affect its productive power in the growth of plants. As a logical result, the man who understands his soil and treats it with sympathetic consideration of its individual peculiarities is in a position to get far heavier crops than he who fails to appreciate the possibility of this co-operation between soil and man. It now seems probable that the soil has a regenerative power that will enable it to produce crops indefinitely, subject to the application of knowledge and skill in its working, instead of being liable to become worked out and exhausted unless a supply of plant food elements, such as phosphorus and potash, is returned in amount equivalent to that removed by the crops

An attempt is made to draw an analogy between the soil and the animal, in view of the concept of the soil as a living entity. The various soil types are illustrated by accounts of the important soils of the United States, indications being given of the crops that are best adapted in each case, with the reasons for this association A proper balance is necessary between what are termed the respiratory, circulating, and digestive systems of the soil for any particular crop to succeed. Methods of soil control are not confined to the replacement of plant food abstracted by crops, but include the proper rotation and adaptation of crops, suitable methods of cultivation, irrigation and drainage, and adequate balancing of organic and chemical manures. After discussion of the conception of the rôle of manures in ancient and modern agriculture, Whitney claims that the time has come to drop the term "plant food" as applied to fertilisers, and pleads for the recognition of the significance of the biochemical factors of the digestive system of the soil and the interdependence and the correlation which exist for the best effort of the soil, the plant, and the fertiliser treatment. In the earlier days of agriculture the responsibility for the maintenance of productivity in the fields rested entirely on the man, but even nowadays chemical fertilisers are not a substitute for human endeavour; they are simply a means of aiding to maintain agriculture in an economic position.

In the cycle of ages, most civilised countries have developed well-organised agricultural systems, many of which have since died out. The cause of this often lay in a change in the character of the people, a substitution of nomadic for sedentary

races, as in Asia Minor and Mesopotamia. Engineering works and irrigation systems were essential for the life of agriculture, and failure to maintain these was often the result of political changes, as in Spain after the conquest. In countries where agriculture has survived, no wars of extermination have occurred. China and Japan have maintained the productivity of their soil by sheer hard work, whereas in Egypt the natural irrigation and increased fertility due to the Nile cannot be de-The agricultural literature of the Romans shows that though the soil was never very productive, intelligence was brought to bear upon cultivation with profitable results The first 1500 years of the Christian era represent the Dark Ages, during which constant warfare precluded agricultural development. After Jethro Tull's advent in 1701 a gradual improvement set in in England, as well as in France and Germany.

Present-day agricultural practice has not advanced greatly over that of the ancients, but more knowledge of material things has been acquired in the last century, as of steam, electricity, chemical elements, etc., and a beginning made in their application. It remains to be seen how the new discoveries will be used. There is every reason to believe we have made only a beginning in the possibilities of research, and it is not outside the bounds of possibility that improvement in important farm crops, as wheat, corn, oats, cotton, may yet be made more commensurate with the development already achieved in animals, in orchard fruits and garden vegetables, by means of intelligent application of the principles of science to agriculture. W. E. B.

# The Analysis of the Reflex.

Muscular Contraction and the Reflex Control of Movement By Dr. J. F. Fulton. Pp. xv+644. (London: Baillière, Tindall and Cox, 1926.) 45s. net.

"Integrative Action of the Nervous System" marked the beginning of a new epoch in neurology. Until then attention had been centred mainly on the analysis of the central nervous system into its anatomical components, the fibre tracts, and nuclei. Their different functions were investigated but very little was known of the way in which these functions were carried out. Sherrington used an entirely different method, the analysis of the complex behaviour of the organism into its component reflexes. Taking the reflex as the basic reaction of the central nervous system, he showed how the

reflexes are compounded and adjusted to make up the changing pattern of activity which we see in the organism in its natural surroundings.

The analysis of the activity of the central nervous system into the constituent reflexes is and must remain for a long time the most potent method of neurological research; but it was clear that the analysis could be pushed a stage further, for the reflex itself is not an irreducible unit but is made up of a complex of activities in the nerve fibres, synapses, and muscles. Not long after Sherrington's book had focussed attention on the reflex, Keith Lucas began an attempt to work up to the reflex from the unit reactions of the nerve fibre. This work was cut short by the aeroplane accident which deprived physiology of one of its most powerful investigators, but its influence has been far-reaching, and in recent years there has been an increasing tendency to analyse the reflex into the simple reactions of muscle and nerve along the lines which Lucas suggested. This tendency is reflected in the present book, which is written by a pupil of Sherrington's on the basis of work carried out at Oxford during the past four years.

To some extent Dr. Fulton works at a disadvantage, in that there is no very clear picture to present. Much work is still in progress on the physiology of the muscular contraction and of the nervous impulse, and although we can see a good way into the processes involved in the activity of the nerve and muscle fibres, we are still in the stage of collecting information and modifying our hypotheses to suit each new piece of evidence. For this reason there is much that is bound to be speculative in Dr. Fulton's presentation of the facts of muscle and nerve physiology, as, for example, in his discussion of the latent period, the summation of contractions, the neuro-muscular junction, etc. There is still more uncertainty when we come to build up a picture of reflex activity out of what is known of the simpler reactions of nerve and muscle. We are still in the throes of a controversy (very well handled by Dr. Fulton) on the nature of the tonic contraction and the relation of the sympathetic system to it, and we have not advanced beyond the stage of multiple hypotheses on the subject of central inhibition. But for all that, the position is clearing rapidly. We know what goes into the central nervous system and what comes out of it, the messages from the sense organs and the messages to the muscles. In every case the message consists of a series of nervous impulses of the type made familiar by investigations on the isolated nerve fibre, and the recent work in Oxford has done much to suggest how the incoming and the outgoing messages are related to one another in the central nervous system.

Although the time is scarcely ripe for the presentation of a complete survey of reflex activity, Dr. Fulton is certainly to be congratulated on the orderly and readable account he has made, both of his own researches and of the great mass of recent work on the many fields involved. Any one who is concerned with the physiology of movement, whether as an investigator, a teacher, or an examinee, will find this book a most valuable (though expensive) collection of recently acquired facts and theories. There is an interesting historical introduction which does not omit due reference to Aristotle, and the book is closed by a table of more than 1000 references. In these days it is hard to overestimate the value of a comprehensive review of this kind, and Dr. Fulton deserves high praise for writing it.

# Our Bookshelf.

The Composition and Distribution of the Protozoan Fauna of the Soil. By H. Sandon. (Biological Monographs and Manuals, No. 7.) Pp. xv + 237 + 6 plates + 3 charts. (Edinburgh and London: Oliver and Boyd, 1927.) 15s. net.

The study of parasitic Protozoa received an immense impetus at the beginning of the century by the increase in our knowledge of certain forms, especially Hæmosporidia and trypanosomes, which are of vast importance in relation to disease of man and animals. In a corresponding manner, the subject of soil protozoology may be said to have been re-born early in the second decade by the work of Russell and Hutchinson and their followers on Protozoa in relation to sick soils. While, however, it is not yet agreed to what extent the Protozoa are, indeed, responsible for diminution in soil-productivity, nevertheless, a new field of protozoological knowledge has been tilled and sown, and some good first-fruits are garnered in this volume.

As Prof. J. H. Ashworth points out, in a specially written foreword, the taxonomic position of the subject can be regarded as already fairly satisfactory, with a record of some two hundred and fifty described species. Two or three new generic or specific names are here created, although this practice in a book is, from the point of view of a recorder, to be deprecated. Under the different classes, the author gives helpful keys for the identification of the various forms, but, as he recognises, in one or two cases, the criteria adopted are to be used with circumspection. In connexion with the account of geographical distribution, the interesting, almost ubiquitous range of many of the species is well indicated by means of tables at the end knowledge respecting the ecology is still disappointingly limited. After discussing the various factors which may influence the numbers and characters of

the protozoan population of the soil, Sandon concludes that none of the climatic or soil conditions considered is capable of explaining adequately the relative abundance of Protozoa in different soils

The book is well arranged and attractively produced, and six plates of figures of characteristic soil Protozoa are given. While, of course, no claim to finality is made for the volume, it is a distinctly needed and useful compendium for those interested in this important subject. H. M. W.

Stories in Stone. Telling of some of the Wonderlands of Western America and some of the Curious Incidents in the History of Geology By Willis T. Lee. (Library of Modern Sciences) Pp xii + 226 + 49 plates. (London: Chapman and Hall, Ltd., 1927.) 15s. net.

The author of this entertaining and beautifully illustrated book did not live to see its publication, but he has left behind him a record of picturesque experience and eloquent enthusiasm. Dr. Lee's work lay largely amongst the extravagant scenery of the western of the United States; while in later years he assisted in the exploration of the great Carlsbad Cavern, and began the study of landscapes from the air. The book reflects a corresponding love for the colourful and spectacular, and in an informal and non-technical way it succeeds in imparting not only the romantic spirit of geology but also a good deal of sound knowledge.

The Grand Canyon is selected as the point of departure because it introduces rocks of the Other pages of earth history are earlier eras. written round the Painted Desert and Petrified Forest of Arizona; the high plateaux and Vermilion Cliffs of Utah; the ice-scuptured Yosemite Valley; and the impressive peaks of the Rocky Mountain National Park. Many of the illustrations are reproductions of photographs taken from the air, and the book as a whole is original in both manner and matter. Teachers of geography will find in it many a telling example, and though its appeal will necessarily be mainly American, it can be cordially recommended to the layman who is looking for a brightly written interpretation of landscape and earth history.

Physiology and Biochemistry in Modern Medicine. By Prof. J. J. R. Macleod; assisted by Roy G. Pearce, A. C Redfield, N. B. Taylor, and J. M. D. Olmsted, and by others. Fifth edition. Pp. xxxii + 1054 + 9 plates. (London: Henry Kimpton, 1926.) 42s. net.

WITH the advance of any science the tendency to specialisation becomes greater and its relationship to, or applications in, other branches of knowledge may be missed unless investigators and teachers can take a very wide view based on facts culled from sciences with which, perhaps, they are not immediately acquainted. Thus the application of physiology to medicine requires an acquaintance with both sciences, which is difficult to maintain when both are advancing rapidly. The aim of Prof. Macleod's book has been to supply the student of medicine with an up-to-date account of the more

important facts of physiology, more especially those which have a direct bearing on the practice of medicine. In this, the fifth, edition the text has been somewhat expanded, so that the work may be used also as a text-book of physiology by the medical student. Dr. Olmsted has added a section on the special senses, and Dr. Redfield has expanded his section on the neuro-muscular system. The application of the latter subject may not at present be apparent in the investigation of disease, yet it is certain that it exists, and it can only be made when the clinician has become familiar with the very latest work. For the medical student or for the practitioner of medicine the book should prove invaluable, whilst for the research worker, further information can be found from the selected references given at the end of each part.

Supplement to an Introduction to Sedimentary Petrography: with Special Reference to loose Detrital Deposits and their Correlation by Petrographic Methods By Henry B. Milner Pp. 156+plates 17-28 (London: Thomas Murby and Co., New York: D Van Nostrand Co., 1926) 9s. 6d. net.

RECENT activity in the study of the mineral composition and derivation of sediments has induced the author, who has given special attention to the subject for many years, to give forth in the form of a supplement to his "Introduction to Sedimentary Petrography," a record of work done since the issue of that book in 1922 The new matter relates to methods of examination as well as to mineral descriptions, the latter including twenty minerals additional to those previously described. The two volumes cover descriptions of seventy-four minerals, fifty of which are illustrated. The illustrations are partly reproductions of washdrawings by G. M. Part and photomicrographs by G. S. Sweeting, all of which are excellent and make a very attractive feature. The supplement contains three appendices, the first of which gives tables for the determination of detrital minerals. The second appendix gives a list of rock-forming minerals which have not yet been recorded as occurring in sediments, but may be expected to be found as the result of further investigation. The third appendix gives a short but excellent and up-to-date bibliography, which is perhaps the most useful feature of the book.

Van Nostrand's Chemical Annual: a Hand-Book of Useful Data for Analytical, Manufacturing and Investigating Chemists, Chemical Engineers, and Students Edited by Prof. John C. Olsen; assistant editor, Dr T. R. Le Compte Sixth issue, 1926. Thoroughly revised and enlarged. Pp xv+882 (London: Chapman and Hall, Ltd., 1927.) 21s net.

Among the many new tables that have been included in this, the sixth, issue of this quadrennial compendium of numerical information, are those of isotopes, hydrogen-ion concentrations, isoelectric points of proteins, vapour pressures of hydrated salt systems and detailed properties of

lead and mercury. The general features of the volume remain unaltered; revision and correction have been effected where necessary, notably wherever the atomic weight of antimony is involved.

Comprehensive as are the lists of physical constants of compounds, one or two of the more recent commercial products have been overlooked, and certain of the organic compounds retain their German spellings. It is questionable whether the inclusion of a large number of problems, so reminiscent of very early examination days, is justified in a work of this character, although the illustrative discussions in this section ("Stoichiometry") are most useful. So far as is practicable, reference is made to original sources of information. Care must be exercised in using tables involving gallons and Beaumé scale, since the book reflects American practice.

Arrhenius is the notable man of science who figures as frontispiece for this issue. B. A. E.

Islands near the Sun: Off the Beaten Track in the Far, Fair Society Islands. By Evelyn Cheesman.
Pp. 236+9 plates. (London: H. F. and G. Witherby, 1927.) 12s. 6d. net.

A FEW months in the Society Islands gave Miss Cheesman opportunities of seeing Tahıti, Raiatea, and Bora Bora, and her experiences and observations are recorded in this delightful volume. It differs from most books on the South Sea Islands in describing not merely the well-populated coast regions, but also the less visited high ground of the interior. Miss Cheesman's main object was to study the insect life of the islands, which was not well known before her visit, and while insects loom large in her pages, she misses nothing of interest in natural history. The book, in fact, is a record of a naturalist's wanderings, written with considerable descriptive power and much appreciation of the beauty of the islands. It is illustrated by a few photographs and sketches by the author. Among the many books on Tahiti it deserves to take a prominent place. There are appendices which give a catalogue of the fauna.

The British Hydracarina. By Chas. D. Soar and W. Williamson. Vol. 2. (Ray Society volume (No. 112) for the Year 1926.) Pp. viii + 215 + plates 21-40. (London: Dulau and Co, Ltd., 1927.)

THE authors are to be congratulated on the completion and issue of this second volume of their monograph so soon—within a couple of years—after the first. This volume is devoted to the systematic description of the water mites of the family Hygrobatidæ. The characters of the ten subfamilies, of the eighteen constituent genera and of the species are carefully defined, with the help of a liberal supply of excellent illustrations These form plates xxi-xl of the work; the first six plates are in colour and all are well reproduced Under each species is given a note of the localities where it has been taken in Britain, and the more general distribution of the species in other parts of the world is indicated by mentioning the countries in which it is known to occur.

# Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### The Sources of Supply of Vitamins A and D.

The problem of an adequate supply of the fatsoluble vitamins for the needs of the growing population has received prominent attention at the recent meeting of the British Association. The shortage in the supply of milk fat in particular was emphasised, and a simple calculation led to the conclusion that this shortage is not a local one in Great Britain, but of world-wide extent. Butter is irreplaceable by margarine as long as this article of diet is deficient in vitamins. Even if we do not share the gloomy view as to the effect of this shortage on the health of the nation, since milk fat is not their only source, it must be admitted that the problem of the supply of fatsoluble vitamins is of outstanding importance.

We would like to direct attention to the outcome of recent researches, only partially published as yet, in the course of which we became aware of easily accessible sources of both vitamins A and D. The solution of the problem depends now only on the industrial application of the knowledge made available by such

research.

So far as vitamin A is concerned, we found that the chromogen responsible for the arsenious chloride colour reaction, discovered by one of us (O. R.), is present not only in the liver of the cod, but also in the livers of all animals examined, fishes, birds, and mammals. A study of the quantitative distribution of this chromogen and its correlation with vitamin A by means of the biological growth-test (Lancet, n. 806; 1926), proved that the amount present in other liver fats in many cases far exceeds that found in cod-liver oil, the richest source of vitamin A previously known. It must be remembered that the main reason for the selection of the cod as a source of medicinal oil, leading to the development of the cod-liver oil industry, was the extraordinarily high fat content of the cod's liver and its relatively easy extraction on a commercial As regards vitamin A content, however, we found that the liver oils of other fishes, such as salmon or halibut, are often more than 100 times as rich as cod-liver oil.

On account of their limited accessibility, these oils cannot be considered as a commercial source of vitamin. The same reason excludes the liver fats of birds, some of which, such as those of the grouse. goose, fulmar petrel (*Biochem. Jour.*, 111; 1927), are extremely potent. The liver fats of herbivorous mammals, on the other hand, appear to be an ideal source of vitamin A. These animals live mainly on green fodder, the original source of vitamin A, and accumulate a store of it in the liver, as do fish and birds. We found by both colorimetric and biological tests that the hver fats of sheep, calf, and ox contain on the average as much as ten times the amount of vitamın A as a good Newfoundland cod-liver oil. Taking the vitamin A content of butter—a very variable factor—as from 1/20 to 1/100 that of cod-liver oil, these fats may be said to be from 200 to 1000 times more potent in this respect than butter. A recently published letter (see Times, Sept. 7) shows that by an interesting coincidence our results in this respect are confirmed by the independent observations, hitherto not published in detail, of Prof. Wilson, formerly of Cairo. According to these, "the liver fats of Egyptian sheep and oxen appear to contain about 200 times the amount of vitamin A found in the best butter examined Without entering into a calculation of the available supply of liver, we may assume that Great Britain's need is easily met at home, supplemented if necessary by Empire produce It may be stated that the vitamin content of the fat obtained from imported New Zealand liver equalled that of the liver of home-killed animals

As an additional advantage for the purpose suggested, we find that these fats are free from the objectional flavour of fish oils, which is apparently connected with the presence of the highly unsaturated clupanodonic acid ( $C_{22}H_{34}O_2$ ) and the Fearon colour reaction (*Biochem. Jour.*, 1342; 1926) Owing to their low melting-point, liver fats can be easily incorporated with other fats, such as margarine. Although easily extracted by the use of fat solvents, their isolation would probably not be necessary in large scale manufacture. Vitamin A, being fat-soluble, can be directly extracted from the tissue by a neutral oil. The wellknown skill of the margarine manufacturer should enable him so to incorporate the liver fats with his product as to convert a dietary article, already identical with butter in calorific value, into a cheap and palatable product of equal biological efficiency, so

far as vitamin A is concerned.

The no less important vitamin D, another variable constituent of butter, remains to be considered. Contrary to the expectation that this would also be contained in the mammalian liver fat, we found that the liver fat of sheep, at any rate, is practically devoid of this vitamin. It would seem that, unlike fish, the herbivorous mammal does not store vitamin D in the liver. On the other hand, the body fats of certain fishes, although free from vitamin A, as tested both colorimetrically and biologically, were found to be a good source of vitamin D. An interesting exception to what appears to be a general rule was revealed in the examination of the body oil obtained from eels. The oil content of this fish is relatively high (about 30 per cent ), and it contains not only vitamin D, but also vitamin A in an amount nearly equal to that of some Norwegian cod-liver oils (tested colorimetrically and controlled by the animal test). This result confirms, medentally, the high value empirically attributed to the eel as an article of diet.

There is, however, no need to search any longer for a natural source of vitamin D, since we are now able to produce this important vitamin artificially by irradiation of ergosterol (Biochem. Jour., 389; 1927). Irradiated ergosterol possesses extraordinarily potent anti-rachitic activity, 1/10,000-1/20,000 mgm per diem preventing and curing rickets in rats. Clinical experience has since shown that human rickets also is rapidly cured by daily doses of 2-4 mgm. The amount to be incorporated with margarine need, therefore, be only extremely small. By a study of the best conditions of its formation in yeast, a practically unlimited supply of ergosterol should be available for this purpose.

The margarine manufacturers have therefore at their disposal, if they care to make use of them, means which should make a perfect biological substitute for butter accessible, without unduly raising the price of margaine. Moreover, by carefully controlled methods of manufacture, it should be possible to supply a product of constant vitamin content, superior in this respect to natural butter, the vitamin content of which depends on too many uncontrollable factors of the food supply of the cow

O. ROSENHEIM. T. A. WEBSTER.

National Institute for Medical Research, Hampstead, N.W.3, Sept. 13.

#### The Mechanism of Formation of the Latent Photographic Image.

A KNOWLEDGE of the process whereby the latent image is produced on the exposure of a photographic emulsion to light is of primary importance to those engaged in fundamental photographic research. For some years past this problem has been under investigation in the laboratories of the British Photographic Research Association, and considerable progress has recently been made in our knowledge of the primary light action.

As a first step, our method has been to try to identify the photographic mechanism with some characteristic of the silver halides which can be studied by purely physical methods, in the absence

of such disturbing factors as gelatin, etc

It has been known for a long time that the silver halides possess both photo-electric and photo-conductivity properties By the former is meant the complete liberation of electrons from the salt under light action, and by the latter the freeing of electrons internally, resulting in a change of conductivity on illumination (sometimes called the internal photoelectric effect). It seemed possible to us that the mechanism responsible for one of these effects might be identified with that which produces the latent photographic image, and consequently we started more than two years ago a series of experiments to investigate thoroughly the two effects in relation to the silver halides, and especially to silver bromide

The results of a long series of experiments which were published (*Phil. Mag*, 3, 482; 1927) indicated that the photographic mechanism was not photoelectric in the sense of its being a complete liberation of electrons from the crystal of silver bromide. The evidence in support of this conclusion is that photographic action takes place in an emulsion made with silver bromide at wave-lengths very much longer than the longest which will produce any photo-electric

emission from that salt

A detailed investigation of the second, i.e photoconductivity effect, has now been in progress for more than a year, and the results already obtained seem to be sufficiently striking to warrant publication in

the form of a preliminary note.

A study of the literature indicated that in many ways a parallelism does exist between photoconductivity and photographic effects. For example, the spectral regions to which emulsions are sensitive photographically are the same on the long wavelength side as those to which the corresponding pure halides show photo-conductivity effects. Take the most important case—that of silver bromide. The photographic spectral sensitivity of a slow silver bromide emulsion increases very rapidly towards the blue from practically nothing at about  $\lambda5000$ . The very trustworthy experiments of Coblentz (U.S. Bureau of Standards, Scientific Paper No. 256) on the photoconductivity of silver bromide showed that this effect also commences in the same spectral region as the photographic effect and increases also towards the blue. To this extent, therefore, the two effects are parallel. Coblentz's results, however, showed a very serious departure from the photographic case in that as the wave-length decreased from \\ \delta 5000, the photo-conductivity effect (for equal energy) after rising rapidly to a maximum, fell practically to zero at about \$\dagger{2}4200. This, at first sight, seemed to indicate that the mechanisms producing the two effects are different, because it is well known that photographic action occurs at wave-lengths far shorter than  $\lambda4200$ .

In the case of such thickly coated plates as are commonly used in photography, there is an apparent

decrease of sensitivity as we pass from the violet to the ultra-violet. This effect has, however, been shown (Phil. Mag, 49, 1104; 1925) to be due, not to a real decrease in sensitivity of the grains of silver bromide, but to secondary effects involving the thickness of the sensitive film Experiments with thinly coated plates demonstrated (Trans. Faraday Soc., 19, 290; 1923; Phil. Mag., 48, 947; 1924) that the photographic sensitivity of silver bromide actually increases on passing from the violet to the ultra-violet. It was thought that the sharp decrease of photo-conductivity in the violet and the apparent absence of the effect in the ultra-violet reported by Coblentz might also have been due to a 'thickness' effect in the specimens used by him and was not an inherent characteristic of the silver bromide.

Since the light absorption by silver bromide increases extremely rapidly with decreasing wavelength from the blue to the ultra-violet, the former light penetrates much farther than the latter into the silver bromide layer. Since, further, the electrical conductivity depends on the whole thickness of the layer, it was suspected that the relative photoconductivity effects at different wave-lengths depends on this thickness, just as we have shown the photographic effect so to depend. Experiments were therefore undertaken to measure the photo-conductivity effects at the three wave-lengths \(\lambda\)4385 (blue), \(\lambda\)4060 (violet), and \(\lambda\)3650 (ultra-violet), and to see whether their relative values varied with the thickness of the silver bromide specimen

employed. Preliminary experiments have completely verified the predictions, and have shown that while with a fairly thick specimen (about 0.7 mm.) the relative order of effects is blue>violet>ultra-violet, yet as the thickness of the specimen is decreased, so the violet and ultra-violet increase relatively to the blue, the order given above becoming completely reversed with a sufficiently thin specimen. The thinnest yet measured is about 0 07 mm. thick, and even for this the effect of a given amount of energy is about twice as great at  $\lambda 3650$  as at  $\lambda 4358$ . Thus what seems to have been the greatest difficulty in the way of demonstrating the identity of the photographic mechanism and that which produces a change in electrical conductivity on illumination, has been removed.

There is considerable experimental evidence that the mechanism of the photo-conductivity effect observed with many crystalline metallic halides involves the loosening of electrons from the halide ions of the lattice. The present work therefore adds considerable weight to the hypothesis that latent mage formation involves the transfer of valency electrons from bromide ions to silver ions, resulting in the formation of metallic silver and free bromine. F. C. Toy.

Physics Department, British Photographic Research Association. (Communication No. 66)

#### The Spacing of Young Trees.

WITH reference to the article on the spacing of young trees in NATURE of July 23, practical foresters in Great Britain might be glad to know the results of any experiments in spacing carried out in high and exposed situations and loose peaty soil While the best results cannot be hoped for under these conditions, the comparative cheapness and unproductive character of land of this class render it tempting for afforestation with sitka spruce and perhaps other

It is obvious, however, that restricted root development and the production of somewhat top-heavy trees are a source of danger where woods are exposed to violent winds. May it not be preferable to space more widely in these cases and raise a crop of admittedly inferior trees, rather than follow the usual recipe and perhaps get the plantation irretrievably damaged after the first thinning? An isolated tree is often extraordinarily storm-proof as compared with trees in the interior of a well-grown wood, but of course its commercial value is small.

It would be interesting to know more of the possibilities and limitations of successful forestry on the bleak high-lying moorlands so common in many parts of Britain. Some of these moors and fells were certainly covered with large timber at one time, to judge from the evidence of place names and the actual trunks uncovered in peat cuttings, but replanting is a difficult problem now that cover is destroyed and the soil either denuded or overlaid with peat bog

EDWARD P FRANKLAND

Needlehouse, Ravenstonedale, Westmorland.

THE article in NATURE of July 23 refers to the possible effect of wide planting distances upon the quality of the tunber to be produced. I can remember the time when the chief criticism to which British forestry was exposed (by those who considered Continental practice ideal for the production of commercial timber in Great Britain) was connected with this very practice of wide planting, associated with or without early thinning. The advocation of the former at the present time would suggest that sylviculture, which at one time was considered by far and away the most important branch of forestry, is to be put into the background for financial reasons The pros and cons of wide or narrow spacing are fairly well known. In the case of species which grow quickly, or under conditions which favour quick growth during the first twenty years or so, close spacing does not always produce satisfactory results, unless early thinning is resorted to. This thinning is, however, under average conditions, unremunerative, and the argument that the expense of thinning can be avoided, and the cost of planting reduced by possibly 50 per cent. through wide spacing, is at any rate plausible enough.

The fact is often overlooked, however, that the question of importance is not altogether one of the number of trees per acre standing five years or so after planting, or which are usually regarded as established. Of far more significance is the uniform distribution of these trees over the surface, so that the competition for space and light is not eliminated in one place and excessive in another. The actual spacing may produce coarser or cleaner poles, obviate or necessitate early thinning, or reduce or increase the initial expenditure, as the case may be, but the final results are in all cases determined by complete canopy or stocking of the total planted area at an early age, and before branch development has proceeded too far for the production of reasonably clean timber.

The condition desired is not so easy to attain as many imagine. The deaths or failures which occur during the first two or three years after planting may be due to a variety of causes, but under average conditions they will occur over a larger or smaller proportion of the total area, and not with the same mathematical regularity with which planting was carried out. But these failures impose a duty on the forester which cannot be neglected if timber of the class and quality capable of commanding an open

market is to be secured. This duty is to thicken up or fill in weak and gappy spots sufficiently early to enable the crop to attain the desired density. The extent to which this may be necessary does not depend upon the original planting distances, but upon other factors which apply to both thick and thin planting alike, but it obviously affects the cost of establishing plantations, and may convert originally low into ultimately high planting costs in the course of two or three years.

If the timber of northern Europe is to be partially or entirely replaced by home production, sylviculture must be considered in the same light as high farming. Costs of production must be studied from a relative rather than an absolute point of view, and cheap planting may not lead to profitable afforestation

A. C. Forbes.

9 Upper Mount Street Dublin.

One of the points in Mr Frankland's letter is answered by Mr. Forbes in his last paragraph, in which he enunciates a correct sylvicultural prescription that sylviculture and high farming are not dissimilar, in that the former requires at least as close a knowledge and practice, and that to curtail expense in the first years is to produce an inferior article which may prove unsaleable at a profit. Mr. Frankland's second point on the subject of the possibilities and limitations of successful forestry on the high-lying moorlands so common in Britain is not at present easily answered since practical experience is almost absent. It may, however, perhaps be stated with some confidence that the solution is unlikely to be found in wide spacmg. To be successfully marketed, tunber from such regions must be of as high a quality as possible. In France, where since the War exposed areas of this type are being afforested, this business is being approached from the viewpoint that close spacing is the first necessity; and that this spacing must be maintained until close canopy has been produced. Subsequent thinnings will probably be delayed owing to the slower growth to be expected, but such thinnings will be carried out as required, irrespective of whether the material is saleable or otherwise.

THE WRITER OF THE ARTICLE.

#### Possible Mechanism of Atomic Disintegration.

The experiments of atomic disintegration (Rutherford, Chadwick, Kirsch, Pettersen, Kara-Michailova, Bieler, etc.) show that by bombardment of  $\alpha$ -particles it is possible to obtain hydrogen emission. Taking the case of heavy atoms, with big nuclear charges, it the  $\alpha$ -particle cannot reach the nucleus, then hydrogen must come from the more external part of the atom.

On the other hand, the experiments of Aston and others show the presence of hydrogen in the discharge tubes: astrophysical observations also show the extraordinary abundance of hydrogen in stellar atmospheres, where atoms are, because of the high temperature, in a state of advanced ionisation. The phenomena are ascertained and so significant that it is necessary to relate them to the atomic structure.

Rutherford and Chadwick have already supported the view that satellites may exist around the nucleus; but to give a satisfactory representation of the phenomenon, I think it may be useful to consider the difference P-2N (used already by Harkins for other purposes, with the name of 'isotope weight'), where P is the atomic weight and N is the atomic number.

I have called this difference the 'excess weight,' and I have thought of it as constituted by P-2N

doublets or dipoles, externally to the atomic nucleus, formed by one positive and one negative electron near enough to have them forming an electrically neutral complex. We may then understand how the number of these dipoles (which must be accommodated in the mtra-atomic fields) must eventually depend on the atomic structure. There are, indeed, some facts that can be related to the present hypothesis and seem to show this dependence

Let us consider the three following magnitudes as functions of the atomic number:

(a) The range of 'variability of isotopes,' namely, the difference between the weights of the higher and the lower isotope of each element,

(b) The 'maximum excess weight,' namely, the excess weight of the higher isotope of each element, or the maximum number of doublets a given atomic configuration can accommodate;

(c) The excess weight calculated from the simple atomic weight

About the range of variability we may remark .

(1) It seems that no relation exists between the range of variability and the atomic number: this fact is very well known.

(2) The range of variability is of well-defined beliaviour in the various groups of homologue elements. these behaviours are generally different when we come to consider different groups of elements.

(3) Radioactive elements have a completely different behaviour from that of non-radioactive elements

(4) Elements following the rare earths group seem to be affected by the difference of atomic structure.

These remarks seem to show that the range of variability of the isotopes depends on the particular nature of the elements, and ultimately, on their atomic structure.

Let us consider the maximum excess weight we may examine the first twenty elements of the periodic system, possessing a relatively simple atomic structure. These elements can clearly show the existence of an eventual relationship between P-2N max, and their atomic structure. Indeed, this relationship exists and P-2N max, has a perfectly distinct behaviour in each period. The greatest deviations of P-2N max happen in correspondence to neon and argon in coincidence with the closing of the 8-electron ring. The following facts stand to show that this coincidence cannot be casual

For the mactive gases and bivalent metals—zinc, cadmium, mercury—P-2N max, doubles each time a given atomic structure is repeated: as a matter of fact, for neon, ending a period of 8 elements, P-2N=2; for argon, ending a second period of 8 elements, P-2N=4, for krypton and xenon, ending respectively a first and a second period of 18 elements, P-2N=14 and P-2N=28; but for radon, ending a period of 32 elements, P-2N=50. For the bivalent metals, zinc, cadmium, and mercury, we get the values 10, 20, 44, we observe then an identical behaviour as for the inactive gases. The remaining elements follow different rules.

The mactive gases and the bivalent metals above mentioned, which follow the law of doubling, are characterised upon the curve of ionisation potentials (L. Rolla e G. Piccardi, Gazz. chim. ital., 56, 512; 1926) by maximum positions and correspond, following Bohr, to complete saturation of electronic orbits (external, in the case of the mactive gases, internal to a 2-electron ring, in the case of the bivalent metals). This also shows that the excess weight does not change casually, but in relation to atomic structure.

We note, therefore, that in passing from the elements of the second short period to the homologues of the first long period, P-2N max, increases from 8 to

12 units, and that going from the elements of the first long period to the elements of the second long period P-2N max increases from 8 to 14 units. In the case of structures growing more complicated, as for the atoms following calcium, it is more useful to consider the excess weight calculated on the basis of simple atomic weight which, among all possible weights, represents generally the most probable one, rather than the excess weight of the maximum isotope we may, in doing so, eliminate many gaps and uncertainties which still to-day limit our knowledge about isotopes

The graph of P-2N shows periodicity in the three long periods—these periodicities point out that the probable excess weight varies in a uniform way in every group of homologue elements.

In an interesting paper by Diaz De Barros (Comptes rendus, 181, 719, 1925) no explanation was offered of the remarkable periodic properties we have pointed out, and the present hypothesis could perhaps, if worked out quantitatively, prove fruitful in developing existing conceptions of nuclear constitution.

#### Method of Manufacture of the Sligo Implements.

An examination of the whole of the material now available makes it abundantly clear as to the general plan upon which the Sligo implements were made (see NATURE, Aug. 20, p 260). The raw material used is limestone, and this rock is present upon the Sligo coast in the form of horizontal layers about 1 foot thick and 13 feet wide. These layers fre-

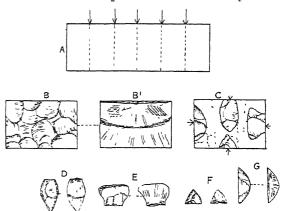

Fig. 1—Diagrams illustrating manner in which the limestone of Sligo was flaked into implements.

quently break with a fracture vertical to their longer axis, thus producing oblong masses of limestone such as is outlined in Fig. 1 (A).

It is evident that these oblong masses were broken into 'steaks' by blows delivered upon the more or less flat upper surface. The method of fracture was probably to hurl a large stone upon any of the points indicated by arrows in Fig. 1 (A), and so to induce a cleavage in a direction shown by the dotted lines. The blocks of limestone thus detached possessed four more or less flat surfaces at right angles to the area of fracture produced, and these surfaces were used as the striking platforms in the next stage of the implement-making process. This stage is shown in Fig. 1 (B), and consisted in the removal of flakes over the whole of one of the larger surfaces of the block of limestone,

by blows delivered upon the four flattish sides other face of the block, Fig. 1 (B1), exhibits the fracture surface, with bulb of percussion produced in the initial detachment of the mass from the parent rock.

Having covered one surface of the block with flake scars, blows were then delivered with a hammerstone at certain selected points along the sides of this surface, and Levallois flakes of various type detached. These are indicated in Fig. 1 (C) by continuous lines, while the arrows show the direction of the flake-removing blows. The original flaking of the surface of the block remaining unaffected by the removal of the Levallors flakes is indicated in Fig. 1 (C) by dotted The flakes so detached exhibit, on their upper surfaces, the truncated remains of the flake scars originally present upon the flaked block, while the under surface shows the bulb of percussion formed when the specimens were removed. After this detachment the Levallois flakes were trimmed to the desired shapes by blows delivered upon the under surface (Fig. 1 (D, E, F, and G)). and this completed the implement-making process.

It will be noticed that this process, as carried out by the palæolithic people of Sligo, bears a very close resemblance to that practised in Mousterian times in the manufacture of flint implements. In fact, the only way in which the Sligo method differs from the other is:

a In the breaking up of the raw material into suitable blocks; and

b. In the detachment of more than one Levallois flake from the prepared core.

These differences are, however, explained first by the differing nature of the raw material, which necessitated the adoption of a different method of preparation, and secondly, by the fact that, having produced a comparatively large area of flaked surface (Fig. 1 (B)), it would have been very wasteful to have detached merely one Levallois flake from it.

Not only is the manufacture of the Sligo implements comparable with that in vogue in Mousterian times. but the forms of the specimens themselves are also clearly the same as those of implements referable to the latter epoch. Lastly, distinct facetting of the striking platforms of some of the Sligo artefacts is observable, while the secondary work along the edges is usually composed of resolved flake scars; and, as is known, both these peculiarities are particularly marked upon implements of the Mousterian period. The Sligo limestone has a marked conchoidal fracture, accompanied by the production of radiating fissures, and this enables the direction in which any particular flake was removed to be ascertained with considerable accuracy.

### Coming British Eclipses.

Dr. HIND published some calculations about the eclipse of June 30, 1954, more than half a century ago. He first announced that it would be total in the northern part of the Shetland group, but afterwards cancelled this, stating that the track would lie a few miles north of the group. I made independent calculations of the eclipse some twenty years ago, but a

numerical error in the final steps escaped notice; this error caused the track to miss the Shetlands, thus confirming Hind I have recently repeated the whole calculation quite independently, using Hansen's tables with Newcomb's corrections for the moon, and Newcomb's for the sun, estimated corrections were applied as follows . +8'' 5, -0'' 8 to the moon's longitude and latitude, +2" 3 to the sun's longitude. The error in my former work was brought to light, the two calculations agreeing perfectly in every other respect. The surprising result emerges that Hind's first announcement was correct; the eclipse is total throughout the island of Unst, and in the northern part of Yell and The point taken for calculation, on the north Fetlar. coast of Unst, is 0° 45′ 7 W, 60° 49′·4 N Totality here lasts 117 seconds, the duration on central line being The sun's altitude is 52° 12' 156 seconds

The conditions are thus extremely favourable, and

it is rather strange that Hind's error has not been detected sooner. The eclipse is also observable in İceland, Faroe Islands, south Norway (Bergen), south Sweden (Oland I.), Memel, Tilsit, Sea of Azov. It is a repetition after three Saroses of the 1900 eclipse (Spain and Algiers); the series gives another European eclipse (Finland and Lapland) in 1990, besides the Constantinople eclipse of 1936.

Some doubts having been ex-

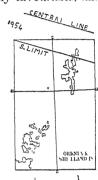

Fig. 1.—Tracks of total solar eclipses of 1954 and 1999.

pressed (notably by Herr C. Schoch, who is an authority on ancient eclipses) as to whether the 1999 eclipse would be total in England, I have recently investigated it, using Brown's Tables for the moon, with corrections of + 18", + 1" 7 in longitude and latitude, and Newcomb's Tables for the sun, with correction +3" in longitude. The result vindicates the almost perfect accuracy of Hind's track published in Nature of Dec. 30, 1875; my track is 5½' south of his, and passes 11½' north of the Lizard. The Rev. J. Maurus Moorat, O.S.B., has kindly made an independent calculation for check, using Hansen's tables of the moon; his track does not differ greatly from mine, but lies a few iniles farther north, thus placing beyond doubt the fact that totality reaches England. In fact, three quarters of Cornwall, the southern quarter of Devon, and a small portion of Dorset about Portland Bill will enjoy totality, as will also a large tract in north-east France. The duration of totality is 2 minutes; the sun's

Comparison may be made of the above results with those of Mahler, which are based on Oppolzer's Canon of Eclipses. Mahler indicates totality in Unst in 1954, his central line being 11 miles north of mine; m 1999 Mahler's central line is about 14 miles south of mine, running through the Lizard. It will be remembered that all Mahler's tracks are decidedly too wide, since he uses Hansen's value of the moon's semidiameter, which is 21" too great for eclipse

<sup>1</sup> A revision of his work makes it practically coincident with mine.

No. 3021, Vol. 120]

purposes. Since the lunar tables used by Oppolzer omit many small terms, Mahler's tracks are uncertain by fully 25 miles, so the discordances found are not

unduly large.

The central lines and limits of totality in these two eclipses are indicated on the accompanying map (Fig. 1). The occurrence of these two favourable British totalities within 45 years of each other is some compensation for the unusually long barren period which has just ended

A. C. D CROMMELIN.

#### The Production of Sound by Heat.

Prof Knipp, in his letter to Nature of Sept 10, seeks for reasons why the 'singing tube' was not discovered long ago by research workers doing their own glass-blowing. In point of fact, it was so discovered. I observed it when making for my father, some vice with the foregroups the context. father some vacuum tubes for examining the spectrum of argon, about 1896. But I found that it had been long familiar to him. He discussed it in a lecture at the Royal Institution (*Proc. R I.*, **8**, p. 536; 1878 NATURE, **18**, p. 319; 1878. Collected "Scientific Papers," vol. 1, p. 350) giving a mechanical explanation similar to that of Prof. Knipp. He had learned the facts from a paper by Sondhauss, which might no doubt be easily located from the Royal Society's catalogue of scientific papers I am, for the moment, away from easy access to a scientific library

RAYLEIGH.

Beaufront Castle, Hexham, Sept. 12.

In an interesting letter on a 'singing tube' which emits a sound when heated at the sealed end near a constriction, Prof. C. T. Knipp gives reasons "why it was not discovered long before by research workers doing their own glass-blowing." However, Sondhauss had a paper in the Annalen der Physik on the subject in 1850 (Vol. 79, page 1). He says at the commencement (I translate): "Many physicists must have observed that bulbs blown on glass tubes of 2 mm to 3 mm. diameter often give out a tone, so long as they are strongly heated; observations on these have been made public only by Pinaud (Pogg. Ann, 42, 610; 1837) and C Marx (Erdmanns Journal fur praktische Chimie, 22, 129; 1841). I had observed the same before Pinaud's publication . . . and was led to take up a more particular study of the phenomenon." Sondhauss rightly considered the source of sound to be the vibrations of the air in the 'singing tube' and gave an empirical formula for the frequency of the tone emitted by a tube having a spherical bulb blown on one end.

I should like to add, from my own observation, that a plain cylindrical tube can be made to 'sing', by means of a hot gauze, even if the latter is placed at a loop, i.e. at the open end of the tube, provided a supply of coal-gas be admitted to the tube and lit just above the gauze. This is known as 'Lissajous' whistling flame,' although I have never been able to trace the reference. By using a lighted Méker burner for the gauze with gas lit above, I was able to produce ear-splitting howls when the burner was placed just beneath the open end of a long brass tube.

E. G. RICHARDSON.

University College, Gower Street, London, W.C 1, Sept. 10.

No. 3021, Vol. 120]

Climatic Changes: Their Causes and Influences.

The evidence for climatic changes in Great Britain about the thuteenth century is not so inconsistent. as Prof Gregory makes out in his reply to Mr Meyer in Nature of Sept. 10. Literary records tend to be comparative (as I have previously explained), so that one would expect most records of droughts to occur at a time when the climate was becoming drier rather than during a time of stable dry climate. Thus, both literary records and the cast Kent watermills discussed by Mr. Meyer point to a rapidly decreasing rainfall in England in the latter part of the thirteenth century. There is probably plenty more evidence of a similar nature buried in old documents, county histories, etc., and only waiting for the spade of the antiquarian.

I cannot claim any direct acquaintance with the sagas, but O. Pettersson appears to have studied them in sufficient detail, and his arguments about the comparative freedom of the Greenland waters from ice in the tenth century have been thoroughly confirmed by the recent excavations at the Eastern Settlement. Absolute freedom from ice is only suggested as a possibility, and not argued as a probability, but I should not care to deny it from arguments about the climate of Britain at that time, for two reasons; first, we do not yet know how or to what extent changes in the ice area off Greenland affect British weather, and secondly, we know practically nothing of the climate of Britain

in the tenth century.

C. E. P. Brooks.

34 Glenhurst Avenue, N.W.5, Sept. 10.

#### Black Sea Earthquakes of Sept. 11 and 12, 1927.

Good records of the above series of earthquake shocks which were felt on the northern coasts of the Black Sea were obtained with the Galitzin seismographs at Kew Observatory In the following table are summarised the times of arrival of the primary phase (P), and secondary phase (S), together with estimates of the times of origin (O), distance of epicentre  $(\Delta)$  and co-ordinates of the epicentre. The centre (A) and co-ordinates of the epicentre co-ordinates have been worked out using Strasbourg and Kew observations, and the figures given are provisional only All times are Greenwich Mean Time.

	Day	Hour	P		S		0		۵	Epicentre
'	Day		m	s	m	s.	m.	s	km	Elucentie
I III IV V V	Sept 11 11 12 12 12 12	22 23 3 6 14 19	21 49 25 38 29 36	2 50 22 43 12 (22)	25 54 29 43 33 40	18 18 46 6 28 (42)	15 44 19 33 23 30	41 13 50 12 51 (55)	2640 2800 2750 2730 2640 (2690)	45° N , 34° E . 15° 5 N , 37° E 45° 5 N , 36° 5 E 48° 5 N , 35° E 45° N , 34° E .

In the case of the first shock, it was possible to make an estimation of the azimuth of the epicentre from the Kew records alone. Using this estimation, the epicentre was found to be 43° N., 34° E. The shocks numbered I. and V. give the largest records, and it is probable that the co-ordinates given of these two quakes are the most correct for the series of shocks.  ${
m \hat{A}n}$  earthquake occurred in the same region on June 26of this year, and the epicentre worked out at Strasbourg was given as 45° N., 34° E.

R. E. WATSON.

Kew Observatory, Old Deer Park, Richmond, Surrey, Sept. 19.

# Telekinesis and Materialisation.

By Dr. E. E. FOURNIER D'ALBE

THERE are certain classes of phenomena, both physical and biological, which for two generations have been persistently pressing for recognition by official science, and have been as persistently refused such recognition With the present worldwide organisation of scientific research, such a situation is, to say the least, unusual. It is not as if new observations were habitually neglected. Quite the contrary The announcement of a new discovery instantly sends a flutter through the universities and research laboratories, and within a week hundreds of competent men are eagerly testing, repeating, and criticising the alleged After a short period of doubt and discovery perhaps controversy, the innovation is either confirmed or discredited, and the attitude of science towards it is settled.

This sifting process is particularly rapid in physical and chemical phenomena, where spurious discoveries are given short shrift. We need only recall the recent 'death-ray' scare to realise the

rapidity and finality of the process.

When a biological or psychological factor is involved the decision is often delayed. It took nearly three years to demolish Blondlot's 'N-rays, and even then the Académie des Sciences awarded him a prize of 20,000 francs for his (more or less futile) researches in a field of unusual difficulty.

In medicine the issue may be in doubt even longer, as in the case of Koch's tuberculin, though the rapid recognition of insulin as a cure for

diabetes is an example to the contrary.

It would be difficult to find cases where facts and their interpretations have been in doubt for more than fifty years. Yet that has happened in the case of the alleged phenomena of 'tclckinesis' and 'materialisation.' They belong to the class of phenomena formerly termed 'occult,' but as this term is too suggestive of the Middle Ages, more up-to-date names such as 'supra-normal,' 'hyper-physical,' or 'metapsychic' have been invented. Currently they are called 'mediumistic,' on account of their association with spiritualism

The word 'telekinesis' was coined by Alexander Aksakow, the first man to attempt to erect occultism into a science. It denotes the movement of objects at a distance without normal means. 'Materialisation' means the formation of organic or inorganic structures from material borrowed from the body of the person in whose presence the phenomena take place, and who is essential to This person is barbarously their production. called the 'medium,' though the word 'psychic'

is often preferred

'Materialisation' was first heard of in 1870, when Mrs. Andrews, of Moravia, N.Y., produced spirit forms.' These were originally supposed to be efforts of disembodied spirits to take on ordinary substance for the purpose of making themselves visible to mortals. No importance was attached to these and similar phenomena by scientific men until 1871, when Prof (later Sir William) Crookes announced his intention to make a series of test The experiments were spread over experiments three years, and led to the most amazing results. which, if corroborated, would have revolutionised

both physics and biology

Unfortunately, they were conducted without those extensive precautions without which, as experience has shown, it is impossible to arrive at a clear-cut decision in these matters himself seems to have felt that he was losing his He abruptly stopped his investigations, and for the rest of his life confined himself to an unprogressive attitude of general assent to the spiritualist position. But his action gave a tremendous impetus to occultism generally, and a succession of famous mediums did their best to reach the pinnacle of D. D. Home and Florence Cook Eusapia Paladino in Italy, Marthe Béraud Eva C.') in France, Kathleen Goligher in Belfast, Willy Schneider in Austria, and 'Margery' (Mrs. Crandon) in America, are the only ones who have been subjected to scientific tests.

Of these, Eusapia stands out as the most remarkable personality. She was born at Minervino-Murge in the Abruzzi in 1854. Orphaned at an early age, she went into service at Naples, and soon got caught in the epidemic of table-turning which prevailed in the 'seventies. At twenty-two she was discovered 'by the Florentine spiritualist Damiani, who had been strongly influenced by the work of Crookes. We accordingly find that Eusapia's chief 'control' thereafter was a spirit called 'John King,' who claimed to be a brother of 'Katie King,' the amiable spirit maiden whom Crookes had embraced at one of his most remarkable séances. At thirty-two she had married a small shopkeeper, but soon she was lifted out of her lowly sphere by the generosity of Cavahere Chiaia, who educated her and afterwards introduced her by open letter

to Lombroso, the famous criminologist.
"Bound upon a chair," he said, "or held tightly by the hands of the curious, she attracts the furniture round her, raises it up, keeps it suspended m mid-air like Mahomet's coffin, and makes it descend in a wavy motion, as if obedient to a strange will. She increases or diminishes her weight av will. She raps and hammers on the walls, the ceiling, or the floor as requested. . . . When her arms are fastened, a third arm appears, nobody knows whence, and plays amusing pranks. It removes hats, watches, and money, rings and pins, and skilfully returns them . . . A large, horny hand, which makes you feel cold down your back, may be grasped, pressed, and mspected, and finally rises and hangs in the air, as if severed at the wrist, resembling the wooden hands hung outside their shops as signs by glove-

This introduction led to the complete conversion of Lombroso, who was eventually persuaded that he had embraced the spirit of his dead mother, materialised through Eusapia's mediumship

Eusapia soon became famous She travelled all over Europe. But she was not always equally fortunate. The Society for Psychical Research found she had a trick of freeing one hand by joining the hands of the persons controlling her But such exposures do little harm to established mediums.

Practically all the well-known mediums have been detected in fraud at one time or other for every such exposure there is a ready excuse The medium is in a state of trance or semi-consciousness, and the controlling spirits are of all kinds, even tricksters When Florence Cook was, in 1880, caught impersonating the spirit 'Mary' in other words, when she was convicted of fraud, the explanation advanced was that it was a 'transfiguration' The supernatural element is introduced at every stage Even when not deliberately mentioned, it is made to influence the investigator in the form of a demand for 'sympathetic' In a word, the application of the scientific method is rendered impossible by making the success dependent upon the whim of a supernatural entity.

During the study of mediumistic phenomena for more than twenty years, I have met most of the famous mediums and have had occasion to defend some of them against what I believed to be hasty and ill-considered judgments. I had great hopes of Eva C and Miss Goligher, thinking they would furnish the groundwork of a new science. But at every step the investigator is baffled by the 'unseen operators'—be they embodied or disembodied—who will not come to a clear-cut issue.

The reviewer in Nature of Geley's "Clairvoyance and Materialisation" says, in the issue of Aug. 27, p. 296: "It seems to me the duty of science either to show that, in the nature of things, there is no inherent possibility for the existence of ectoplasmic matter, or to attempt a tentative explanation of the phenomena" I regard the former alternative as impracticable. Who can set a limit to the possibilities of the organic world? Every individual born is a new experiment, and none can say what strange beings may yet be produced, or with what wonderful faculties they may be endowed.

If we must have a tentative explanation, there is one ready to hand. The alleged phenomena of telekinesis and ectoplasm are all spurious, and are due to faulty observations or faulty conditions How difficult the conditions of the average séance are can only be realised by practical experience illumination is of the order of 0 001 foot-candle, and is usually considerably over-stated. observer is wearied by hours of strained attention without anything happening Often the sitting is entirely barren, and before the next sitting he will naturally examine his conscience to see whether an undue insistence on evidential conditions may have inhibited the phenomena. So he relaxes them. Then he gets phenomena. But they are no longer evidential

Out of the large array of mediums who have

shown the phenomena of 'teleplasm' or 'ectoplasm.' only three have been investigated under scientific conditions. Dr Baron von Schrenck-Notzing spent several years in studying Eva C. He gives the following description of ectoplasm

"The Ectoplasm on further condensation becomes white and transforms itself into amorphous coagulated masses or packets, or assumes the structure of the finest web-like filmy veils. Sometimes the veil-like forms are doubled over at the margin, so that the first impression is that of a stitched hem. The veils never show the Characteristic square thread-work of real veils.

"The pieces look like torn shreds of fabrics, or like ribbons, strings, or long fibres, or again like low organisms. . . . The mass seems to pass freely through the lighter materials of the dress, penetrating them, perhaps in a vaporous form, and subsequently condensing in the form of grey flakes

"The experiences with Eva C show many correspondences with the phenomena of Eusapia Paladino. The symptoms of mediumistic labour and its muscular accompaniments were found in both persons. The same utterances of pain, the same moaning and pressing, the same effort of will."

On two occasions Dr von Schrenck-Notzing was able to obtain samples of the substance, and subject it to analysis. The first sample was indistinguishable from human skin such as might be peeled off a human heel. The second sample closely resembled saliva in its microscopical character.

In March 1922, Eva C. was investigated by a committee appointed by the Psychological Institute of the Sorbonne This committee reported that what phenomena there were could be produced by regurgitation. The same result had been arrived at by the London Society for Psychical Research in 1920.

The case of Kathleen Goligher resembled that of Eva C in many particulars, but her phenomena were unaccompanied by the signs of physical distress exhibited by the other mediums. Dr. Crawford published numerous photographs, which strongly suggest the textile nature of the substance This was established by me in 1921, when I succeeded in taking the only contact photographs of ectoplasm ever obtained. They were taken by putting the photographic plates on the floor under the table and requesting the 'operators' to place some ectoplasm upon them. When all was ready, a small electric lamp fixed on the under side of the table was switched on for a few seconds. The results showed the unmistakable structure of chiffon or a similar material.

Quite recently another case of materialisation, in connexion with 'Margery' (Mrs Crandon), was investigated by Mr E J Dingwall He found the materialisations resembling animal tissue 'The appearance," he says, "suggests something analogous to lung tissue, and the smell of the substance which, according to Dr. Worcester, resembled the

smell of the entrails of a freshly killed animal, pointed in the same direction."

There is nothing in all this to make out a plausible case for the assumption of a new substance called 'teleplasm' or 'ectoplasm' It is impossible to extract from the literature on the subject any consistent description of its supposed properties In the days of Katie King, the apparition was able to cut off portions of her dress and distribute them to her audience, who found that they resembled ordinary calico. Nowadays the substance is supposed to be very fugitive and sensitive to light. The hypothesis which seems to cover all the facts is that a succession of mediums, under pressure from sitters anxious to see marvels, have produced these 'spirit forms' by trickery. This trickery has become increasingly difficult and has practically disappeared whenever test conditions are applied. It is, therefore, impossible to admit the existence of any new facts, and even a tentative explanation of them is uncalled-for. Science might just as well concern itself with the anatomy and physiology of fairies.

There is another matter which must not be overlooked. The forces behind occultism and supernaturalism are very powerful. They are based upon the very human craving for the mar-

vellous All religions contain this element, and promote it in various ways. There is a tendency in modern times, especially in America, to link religion with science, so as to utilise the growing prestige of the latter. The funds available for the enterprise of winning the approval of science for the modern miracle are very considerable. A wealthy French spiritualist recently established and endowed an International Metapsychic Institute in Paris, and appointed as its director a local practitioner of spiritualistic sympathies, Dr. Gustave Geley. The publication of his conclusions and speculations in an imposing and expensive volume formed a very telling piece of propaganda.

Such institutions form a kind of spearhead forged by occultism for piercing the armour of science, and it would not be surprising to see the foundation in England of an Imperial Academy of Natural and Supernatural Science, generously endowed from British and American sources—Its prospectus would be liberally sprinkled with the names of Crookes, Lombroso, Richet, Flammarion, Geley, Crawford, and von Schrenck-Notzing, and everybody would know that science had at last become 'spiritualised' and centred in other worlds than ours; and sacerdotalism, having been expelled by the door, would come back through the window.

# Base Exchange and the Formation of Coal.

By Dr. E. McKenzie Taylor.

DURING a soil survey of the northern portion of the Nile Delta for reclamation purposes, a deposit of vegetable debris was discovered at a depth of two metres below the soil surface. As this deposit was found to contain peat, fusain, and partially fusainised material, an association that does not appear to have been recorded previously, it appeared that an investigation of the conditions under which the deposit existed might afford evidence of the mode of formation of coal. It is accepted that coal has been formed from vegetable material, and it has been generally assumed that the vegetable material accumulated as peat. The connexion between peat and coal has, however, not been established.

An examination of the soil overlying the vegetable layer in Egypt showed that it was alkaline and that the principle replaceable base present was sodium. The soil had originally been formed by the deposition of Nile silt in which the main replaceable base is calcium. The conditions under which the soil was situated showed that the conversion of the calcium-clay in the Nile silt into sodium-clay had taken place as the result of base exchange with sodium chloride solutions, and that the alkalinity had been produced by the subsequent hydrolysis of the sodium-clay in fresh Investigations in the laboratory have shown that it is possible to maintain the alkalinity of a medium for a considerable length of time by the hydrolysis of sodium-clay. It has also been shown that a roof containing hydrolysing sodiumclay is impermeable to gases and water, that the conditions under such a roof are anaerobic, and that

the alkaline medium produced under such a roof is suitable for the continuous bacterial decomposition of organic matter.

A study has been made of the bacterial decomposition of organic materials under the alkaline anaerobic conditions furnished by a roof containing sodium-clay. Sugars, starch, and cellulose decomposed under these conditions yield gaseous products only, the gas produced accumulating beneath the roof. An examination of this gas showed that it was principally methane, the carbon dioxide produced during the decomposition having been absorbed by the sodium hydrate resulting from the hydrolysis of the sodium-clay. Mature leaves were submitted to bacterial decomposition under a sodium-clay roof. The residual solid product was black and possessed the typical fusain structure. Analyses of the leaves at intervals showed that elimination of oxygen was taking place and that the process of decomposition was continuous. The bacterial decomposition of peat under a roof containing sodium-clay was also investigated. It was found that peat could be decomposed under the alkaline anaerobic conditions, that the alkali-soluble 'humus' in the peat was removed in solution from the seat of the bacterial action, and that the gas accumulating under the alkaline roof was methane The investigation of the bacterial decomposition of organic materials under a roof containing sodium-clay has shown that bacterial activity in the continuously alkaline medium is not inhibited by the accumulation of toxic products of the decomposition and that the solid residue is a reduction product. It has also

shown that peat can be decomposed under alkaline anaerobic conditions

As peat can be decomposed by bacteria under an alkaline roof, and as vegetable material decomposed in such a situation yields a solid reduction residue with a fusain structure, the occurrence of a peat deposit containing fusain under an alkaline soil points to the conclusion that fusain is a decomposition product of peat under the alkaline anaerobic conditions imposed by a roof containing

hydrolysing sodium-clay

Since fusain is a constituent of bituminous coal, it seemed probable that bituminous coal might have resulted from the bacterial decomposition of vegetable material under alkaline roof conditions A considerable number of specimens of the roofs of coal seams in Great Britain were examined, and it was found that the great majority were alkaline and that sodium was the main replaceable base The exceptions to these rules were of two main types (a) coarse-textured shales or black sandstones, and (b) white sandstones and con-The final result of the hydrolysis of glomerates sodium-clay is the production of an unsaturated clay with an acid reaction. If the amount of reactive clay present in the roof was originally small, complete hydrolysis is likely to have taken place under fresh-water conditions with the formation of an unsaturated residue with an acid The coarse-textured shales and black sandstones would contain comparatively little reactive clay material, and hence the sodium compound would be liable to complete hydrolysis The first exception is apparently due to the complete hydrolysis of the sodium-clay originally present. The second type of exception is of local occurrence only and is usually in the nature of a wash-out, indicating that the sandstone or conglomerate is not the original roof of the seam. Frequently the sandstone is underlain by a thin shale layer. From a consideration of the results, it appears that the original roofs of bituminous coal seams have undergone base exchange with sodium chloride solutions, and that afterwards the sodiumclay has undergone hydrolysis in fresh water.

An examination of the roofs of the anthracite coal seams of South Wales has shown that they are also alkaline and contain sodium-clay, indicating that the anthracite in the South Wales coalfield has been formed under similar final conditions

to bituminous coal.

The results of these investigations point to the conclusion that bituminous coal has been formed as the result of the bacterial decomposition of vegetable residues under the alkaline anaerobic conditions imposed by a roof which has undergone base exchange with sodium chloride solution and subsequent hydrolysis of the sodium-clay in fresh water.

An examination of the roofs of a number of lignite seams has also been made. It appears that the main replaceable base present in the roofs of lignite seams is calcium, indicating that the roofs of these seams have not undergone base exchange with solutions of sodium chloride. Lignite is therefore not necessarily an intermediate product

between vegetable matter and bituminous coal, but is rather a decomposition product of vegetable matter under a roof containing calcium-clay.

As bitummous coals and anthracite occur in different parts of the same seam and under the same roof conditions, it is suggested that the difference in the final decomposition productsbituminous coal and anthracite—is due to differences in the material submitted to bacterial decomposition under the final alkaline anaerobic conditions It is not necessary to assume differences in the original plant materials to account for this. Differences in the decomposition products during the 'peat stage' may have arisen due to variations in the conditions of the first decomposition. This would result in a variety of products being submitted to the final decomposition under alkaline anaerobic conditions giving rise to the variety of final products composing the bituminous coal-anthracite series

Base exchange between sedimentary deposits and solutions of sodium chloride can take place under three conditions in Nature: (a) by deposition of the silt in sea water, (b) by submergence in sea water of a deposit already formed, and (c) by the reaction of the clay with capillary solutions of sodium chloride raised from a water-table containing that salt Geological evidence of base exchange under conditions (a) and (b) will be positive. Under condition (c) there will be no geological evidence of base exchange, determinations of the pH value and the nature of the replaceable bases being the only evidence on which to base a conclusion. From the examination of the roofs of the coal seams in Great Britain, it appears that the majority of the roofs have undergone base exchange with capillary solutions of sodium chloride.

The presence of the alkaline roof satisfactorily accounts for the observation that coal seam gases mainly consist of methane. Oxygen elimination from the vegetable material must have taken place during coal formation, but no appreciable quantity of carbon dioxide has been recorded in coal seam gases. The carbon dioxide produced by the oxygen elimination would be absorbed in the sodium hydrate solution resulting from the hydrolysis of the sodium-clay leaving a methane residue.

Three main conclusions concerning the formation of coal may be drawn as a result of this investigation:

(1) The vegetable material accumulated as peat. (2) The roofs of bituminous and anthracite coal seams have undergone base exchange with sodium chloride solutions, the sodium-clay being afterwards hydrolysed in fresh water. This would provide an alkaline medium under anaerobic conditions for the bacterial decomposition of peat.

(3) The decomposition of peat under a roof containing calcium-clay results in lignite formation.

The roofs of bituminous coal seams other than those of the Carboniferous System are being investigated. The results so far obtained indicate that base exchange between the roof and sodium chloride solutions is common to all bituminous coal seams and forms the connecting link between the coal seams of the various geological formations

# The Ancient History of Sponges and Animals.1

By Dr. G. P BIDDER

T is not fitting for one who is not a geologist to do more than touch very lightly on the prob-But connected with lems of the pre-Cambrian them is an interesting consideration to which I would direct the attention of fellow biologists. If we follow the American geologists in attributing organic origin to the graphites of the Grenville series at the base of the Laurentian—which are stated by Dawson to contain as much carbon as the whole American coal-measures, and with which we may class the graphite schists described by Geikie under the Scottish Lewisian, and the seven feet of socalled 'anthracite' found in Finland by Sederholm in the Jatulian, at least two miles under the Cambrian—I do not see how we can avoid the conclusion that there was vegetation growing in or about quiet landlocked waters, for many thousands of years, as long before the Cambrian as the Cambrian was before us. Among palæontologists the view prevails that it is in such still landlocked waters that rapid evolution has always taken place. It seems impossible not to believe that a terrestrial flora, and a terrestrial fauna, must have been evolved in those favourable times and the long ages which followed, to be swept to destruction in the deluge that denuded the Torridonian. If so, we see in the succession of Cambrian and Ordovician fossils—the 'marine period' of the Palæozoic, as Marr designates it—the development for a second time of a littoral from a deep-sea fauna, which fits closely with Walcott's conclusions on the Cambrian, and in the Silurian and Devonian we see the evolution of a terrestrial flora and fauna for the second time.

If all the pre-Cambrian lands were swept by fierce and terrible torrents, marine organisms might nevertheless survive in the deep abysses of the sea, to recolomse later the still-vexed Cambrian shores. It is also conceivable that exceptional organisms might survive in the tranquil abysses of the high air, or on the occasional mountain-tops; and the fancy has struck me that such isolated survivors from the ancient sub-aerial population may conceivably be recognised in the progenitor of the Ordovician winged insects, and also in the ancestor to Hugh Miller's conifer of the Old Red Sandstone.

Leaving the geologists and botanists to settle for us the truth or error of the premisses, the argument does not seem without philosophic interest:—that if the 7-foot graphite bed in Finland be of organic origin, there may be a class or classes of terrestrial animals or plants which have breathed air two or three times as long as those which left the sea in the Devonian.

The Laurentian coal, if coal it be, must mark the climax of a long evolution in the seas of the still earlier pre-Laurentian, and in that part of our history must come the primary advance which Church has rightly taught us to regard as the

 $^1$  From the presidential address to Section D (Zoology) of the British Association, delivered at Leeds on Sept 1.

greatest step in evolution, the evolution of the flagellates Church claims that, since protoplasm appeared, we may fairly estimate half the time elapsed as being required for the evolution of the flagellate. If Dr. Church measures his time in years, the geological record seems difficult to fit, for the chetopods, molluses, crustaceans, and echinoderms of the Cambrian are clearly very old But the single step in evolution is not a year but a generation, and there may well have been as many generations of our ancestors before they became flagellates as there have been since we have been multicellular. If we have been 'higher animals,' averaging ten generations a year, for 1000 million years, then some 10,000 million generations may have brought us from jelly-But 1000 generations a year would fish to men be a very moderate number for flagellates and preflagellates, so that 10 or 20 million years would give them as many steps in evolution, to make a flagellate from nothing, as it has taken us to build up a flagellate into man.

We are still lacking a satisfactory account of the early ocean in which those fateful 20 million or 200 million years were passed, and in which life began. I suggest as a working hypothesis for biologists that, since the pre-Cambrian, there have been no variations in the mean salinity of the ocean so great as the difference between the salinity in the Mediterranean and in the North Sea ocean was more or less saline: it was also soaked with carbon dioxide. In the air there was no oxygen, but nitrogen, much water-vapour, and carbon dioxide in large quantities. Life is the history of high earbon compounds, in which every atom of carbon has been in a molecule of carbonicacid gas. Volcanoes and springs have always been pouring into the air carbon dioxide from the bowels of the earth, coal-plants and calcareous animals have buried in solid form the carbon from many thousand times the quantity of carbon dioxide which we have now in the atmosphere; it is therefore probable that the alkalinity of the sea, and the dissolved calcium, have varied considerably from epoch to epoch. If all the surface of the globe were one continuous meadow, evenly producing a ton of hay an acre annually, I make out that in twenty-five years it would have fixed as much carbon dioxide as there is in the atmosphere, and in 15,000 years it would produce as much free oxygen as we have in the world to-day

We see, therefore, that the advent of photosynthetic protein in the ocean must itself have changed the physiology of the world very considerably, and that the change in conditions, after a million years' duration of the lowest form of life, rendered the world capable of supporting organisms which would have been impossible at the beginning of that age, and conceivably rendered it incapable of supporting ever again the first forms of life

Of the possible genesis of the first form of life we

heard from Dr Allen at Hull. To-day let us take up the tale, in the warm pre-Laurentian sea, with little fragments of protein lying in the sunlit waters Each fragment is continuously receiving energy—whether from the sun, according to Prof Baly's theory of activation, or from some other electromagnetic source—and with that energy is building up the molecules of the surrounding solution into molecules of protein, so that the fragment grows.

The supply of energy is continuous, and the supply of solution is continuous, yet growth of the fragment of protein cannot be continuous, because number is discontinuous. A growing fragment contains 100 molecules of protein, presently it will contain 101, then 102. It may be a thousandth of a second, it may be an hour between the moment of attaining 100 and the moment of attaining 101 molecules, but with a constant supply of energy it will be closely the same interval after acquiring the 101st molecule and before the 102nd is added Let us suppose that the interval had been 10 seconds. What will be happening during the next 10 seconds before the molecules number 103?

The continuous supply of energy must in some form be stored in the 102 molecules until its total is adequate to compel the combination of the water, carbon, nitrogen, sulphur, and the rest of it into the new 103rd molecule of protein. This stored energy is then spent in forming the combination, and for another 10 seconds the 103 molecules accumulate gradually a sufficient supply to force the combination of a 104th molecule We cannot suppose that the molecules can store energy except by a change of atomic or electronic arrangement, or that such change fails to affect their molecular volume. Expansion of molecular volume means storage of energy which is released on contraction; we may feel sure that even if the main storage of energy be in some other form, it will at least be accompanied by expansion in volume and surface. When energy is given up to form the new molecule, all the old ones will return to their original volume, and if their expansion was by more than onehundredth of their volume, the whole fragment will

A slow expansion while energy is being accumulated, a rapid but smaller contraction when the new molecule is formed, so these fragments of protein pulsate steadily through the day. So they continue through the ages, while protein enters into new combinations, and the aggregate of protein molecules is replaced by a unit of protoplasm, still keeping the rhythm of saving up energy and making-a-molecule, saving up energy and making-a-molecule.

Now protoplasm in most organisms which we can study becomes altered at the surface which is in contact with water, by a change which is conveniently called 'gelation,' the protoplasm at the surface losing most of its fluidity and changing in other properties. In certain circumstances, such as increased salinity of the water, the internal fluid protoplasm will burst out through this gelated surface in fine threads, which either gelate in their turn or change into strings of drops.

I venture to suggest that the great evolution of the flagellate, which Church pointed out to us, accomplished in some ten thousand or hundred thousand million generations, was the formation of a permanent filament of protoplasm of which one side was more gelated than the other side, so that one longitudinal strip of the cylindrical outer surface is more elastic and therefore less easily extensible than the opposite strip Let us suppose the gradual accumulation of energy causing, as before, a gradual increase in volume of the protoplasm, then the more easily extensible surface will swell, and therefore lengthen, and the filament will gradually bend When the quantum of energy is reached which suffices for formation of a new molecule, every old molecule will suddenly lose its surplus energy and return to its old molecular volume, the distended surface will return to its old dimensions and the filament will straighten.

I have spent an appreciable part of my life watching the flagella on the living collar-cells of Calcareous sponges-Grantia, Sycon, Leucandra, and Clathrina Their movement is nearly confined to one plane and is asymmetrical, being almost always with a faster beat to one side than to the other. There is a pause, a stroke, and a counterstroke Mr James Grav pointed out to me that if the counterstroke be elastic, as I supposed, it should always take the same time, as compared with the varying time of the active contraction This I found to be the case. At about 2½ double vibrations to the second, the stroke and counterstroke are of equal duration, at higher frequencies the stroke is the shorter, as in a schoolmaster's cane; at lower frequencies the stroke is the longer, as in a fisherman's trout rod. The broad features of the phenomena are therefore consistent with the hypothesis that the counterstroke is an elastic rebound.

The apparent improbability of a lowly-organised cylindrical cell, with an axial straight flagellum, having one longitudinal strip of the surface of that flagellum different from all the rest of that surface, disappears when we recognise that one longitudinal strip has a different history from all the rest of the surface. A collar-cell in a sponge is usually surrounded on all sides by six other collar-cells, of which one is its twin sister. Like all flagellates, ıncluding metazoan spermatozoa, collar-cells dıvıde longitudinally. The details of this division were worked out very beautifully by Miss Robertson and the late Prof. Minchin; and they showed that the little bead at the base of the flagellum, known as the blepharoplast, is the first thing in the cell to divide, and forms two daughter blepharoplasts which take the part of centrosomes and induce the division of the nucleus into two daughter-nuclei, followed by the division of the cell into two daughter-cells. In each of these daughter-cells the new blepharoplast grows a new flagellum will be seen that the part of the blepharoplast which was last in contact with its sister is, as it were, a healed wound, and the strip of flagellum which grows from this has therefore a different parentage from that which grows from the opposite surface of the blepharoplast, which is an intact part of

the parent surface.

There is no nervous system in sponges, and no sign of nervous control of the flagella, either from the individual cell or from the community direction and timing of their beat is wholly uncorrelated, and though the frequency of two neighbouring cells generally approximates to equality, it is not exactly the same. The frequency varies when the temperature and soluble contents of the water vary Except in certain cases where a wandering ovum (Grantia) or porecell (Clathrina) is laid over a collar-cell. I have never seen a flagellum motionless in a cell which was not moribund. I believe the motion to be ceaseless, unconscious, and uncontrolled, a direct function of the chemical and physical environment

What has this to do with the history of animals? Our ancestors were flagellates, or lower than flagellates, for as many generations as they have been anything else, for perhaps five or fifty times as many generations as they have been vertebrates, at least two hundred times as many generations as they have been mammals, and our ancestors were flagellates for at least five thousand times as many generations as they have been men. All those flagellate ancestors of ours passed their whole active lives in this continual rhythm of accumulating

energy and building, accumulating energy and building, twenty or more to the second through the whole of their short lives Is it likely that we have forgotten that rhythm? I believe that all through our growth, from infancy to prime, we added our molecules to every unit of protoplasm, rhythmically, as our flagellate ancestors did. When we have passed our prime, our units keep their rhythmic reconstruction; only now, because we are land-animals and must not grow any bigger for fear that our limbs should snap, the rhythm or the chemical change is readjusted, so as only each beat to add as many molecules as we use up between the beats. But the adjustment is not perfect, so that when we have done growing our protein units do not keep absolutely constantthey lose a little each beat on the balance of gain and expenditure So that as we grow older our muscles shrink, and our nerves shrink, and our cartilages shrink, and our brain shrinks, and we become what other people call 'semile', and at length we die—a thing which none of our twelve thousand million flagellate ancestors ever did.

Incidentally, I believe that to that same metabolic rhythm, inherited from the flagellates, we owe our sense of time, so that our appreciation of dancing, poetry, and music shows that we are still

flagellates at heart.

# Obituary.

MR. E W. FERGUSON.

SCIENTIFIC circles in Australia have suffered a great loss in the death at Walnut great loss in the death at Wahroonga, New South Wales, on July 18 last, of Dr. Eustace Ferguson. Eustace William Ferguson was born at Invercargill. New Zealand, in 1884, the son of the distinguished divine, Rev John Ferguson of St Stephen's, Sydney, and when an undergraduate of the University of Sydney showed a passion for natural history. He was encouraged to collect coleoptera by Mr. George Masters, Curator of the Macleay Museum, in whose room I first made his acquaintance. Graduating in 1908 with honours in medicine, he showed an unusual knowledge of that side of his work which dealt with zoology and microbiology. He joined the Linnean Society of New South Wales in 1909 and contributed his first entomological paper on the Phalidurinæ, or ground weevils of Australia, in which group he became the authority; in all he published fourteen papers on the group, papers that were distinguished by their lucidity and judgment.

Joining the Department of Health of New South Wales as pathologist, Ferguson succeeded Prof. Cleland as chief microbiologist; and in logical sequence his later entomological work took a medicinary turn. He was soon keenly engaged in the study of mosquitoes, biting flies (Tabanidæ), fleas, and ticks. Here, as in the field, he showed a remarkable power of close observation, which, combined with a retentive memory, enabled him to recognise at once any form, however minute, that he had once examined. As the companion of many a delightful collecting trip, I have never met his equal for keenness of sight and notice of detail in natural objects.

Ferguson possessed a wide knowledge of Austrahan birds—whether on land or sea From 1915 until 1918 he served in the Medical Corps of the A I.F. in France, Egypt, and Palestine, using his opportunities to visit the Natural History Museum to study types of Australian insects; while in the East he was greatly interested in the history and archæology of those lands He contributed some half dozen papers on the Diptera—chiefly on the Tabanidæ and Syrphidæ—to the Linnean Society of New South Wales, and used his influence with other specialists to communicate some sixteen valuable papers by them to the same society between 1922 and 1927—papers largely founded on material supplied by himself.

Ferguson was a member of the council of the Linnean Society of New South Wales from 1921, and its president in 1926—during the November of which year he was attacked by his fatal illness, actually writing an able presidential address, "A Review of Medical and Veterinary Entomology in Australia," on his sick-bed He was also a member of council and president in 1922 of the Zoological Society of New South Wales, his address containing a strong plea for a biological survey of Australia. In his Department he organised "Tests for the Susceptibility to Diphtheria," and wrote a valuable Report on Dengue Fever. He leaves a widow and six children, five sons and a daughter.

H. J. CARTER.

#### Mr. S. R. Wilson.

THE news of the accidental death, at the early age of forty-five years, of Sidney Rawson Wilson while carrying out an experiment with nitrous oxide has given a painful shock to his many scientific and medical friends

Wilson was the son of Arthur Cobden Jordan Wilson, of Penistone He had a brilliant career as a student at Manchester, during which he obtained the Junior and Senior Platt Physiological Exhibitions and the M.Sc (Vict.) in physiology. Thus early he showed an interest in physiology which remained unabated throughout his life. He afterwards took the M B. degree, both at London and at Manchester, in both cases with honours, and the F.R C S. Edin

Professionally, Wilson was one of the first to make anæsthetics his speciality, and he always endeavoured to combine scientific investigation along with its practical applications He developed the use of the combined administration of oxygen and nitrous oxide for prolonged anæsthesia and introduced improvements in the method of ether The use of carbon dioxide as a administration respiratory stimulant, the importance of which has been emphasised by Yandell Henderson in America, was another of Wilson's contributions to practical anæsthetics. This year he published a paper on ether 'convulsions, the first scientific contribution to the elucidation of this new and dangerous phenomenon

Although previously noted in workers in paraffin refineries, Wilson collected evidence so early as 1906 of the occurrence of cancer of the scrotum in mule spinners. His work on this disease won the Tom Jones Surgical Scholarship in 1907. In 1922 he published a joint paper with Mr. A. M. Southam on this condition, and in 1926 the report of the Home Office Committee on mule spinners' cancer gave him credit for this pioneer work.

News and Views.

THE notice of Dr. Gustave Geley's book on "Clairvoyance and Materialisation," in NATURE of July 23, seems to have been understood by some readers as signifying acceptance of the demonstrable existence of what is known as 'ectoplasm.' Mr. Campbell Swinton expressed the general scientific attitude upon this subject in a letter to NATURE of Aug. 27, and the reviewer, "W. W. L.," then explained that what were described as "facts of experience" in the notice are not necessarily scientific facts capable of being repeated and demonstrated at will. Whether statements about psychical manifestations related by uncritical observers, or similar evidence of 'ectoplasmic' structures, are accepted as 'facts' at all, depends largely upon the tendency of the listener or reader to believe or to doubt. The distinction is aptly drawn by Cowper in his poem "Conversation" in the words:

On the mauguration of a new course in human physiology in the Manchester School, Wilson gave, although in the midst of many professional demands, unstinted help in the development of this teaching and in the carrying out of both human and animal experiments These led him to try out fearlessly their results on his own person. He had early this year maugurated research on the problem of how far nitrous oxide possesses specific anæsthetic properties apart from its action as an oxygen diluent in producing anoxemia. Indeed, it was this work that led him to undertake the experiments which resulted in the fatal accident and deprived the Manchester School of an untiring and intrepid worker.

Wilson took a deep interest in the special senses and in the physiological interpretation of hypnosis. Recently he had initiated work on the retinal sensitivity to the red end of the spectrum, in the course of which he discovered some remarkable phenomena and was engaged in their elucidation during the early part of this year. Recognition of his work by American colleagues gave him great pleasure, and he did much to open up co-operation between the workers in the two countries Besides contributing to the medical journals he took a large part in the foundation of the British Journal of Anæsthesia. He leaves a widow, son, and daughter to mourn his loss.

WE regret to announce the following deaths:

Dr. Bruce Fink, since 1906 professor of botany in Miami University, an authority on lichens, on July 10, aged sixty-five years.

Sir William Glyn-Jones, from 1919 until 1926 secretary of the Pharmaceutical Society of Great

Britain, on Sept 9, aged fifty-eight years. Prof. R. A. Lehfeldt, professor of economics in the University of the Witwatersrand, Johannesburg, since 1917, and formerly professor of physics in East London College and also in the South African School of Mines and Technology, aged fifty-nine years.

Assertions as to the real nature and physical pro-

perties of 'ectoplasm' are received by most natural philosophers in the sceptical frame of mind expressed in these lines. So much attention has, however, been given to the subject in recent years that we invited Dr. Fournier d'Albe, who translated Schrenck-Notzing's "Phenomena of Materialisation" (see NATURE, Nov. 18, 1920, p. 367), to contribute an article upon the actual evidence for the existence of what has been alleged to be an incipient type of matter; and his contribution appears elsewhere in this issue. It will be seen from this article that Dr. d'Albe regards all the alleged phenomena of ectoplasm as spurious. This conclusion of a physicist who has devoted many years to psychical research and spiritualism must carry more weight in a court of natural science than that of many witnesses not possessing his experience in careful observation and cautious conclusion.

In Heft 4, Bd. II. (1927) of the Zeitschrift für kritischen Okkultismus, Dr. d'Albe has supplemented

<sup>&</sup>quot;Can this be true?" an arch observer cries:
"Yes" (rather moved), "I saw it with these eyes."
"Sir! I believe it on that ground alone;
I could not had I seen it with mine own."

his unfavourable report of the alleged mediumistic phenomena occurring with the Irish Goligher Circle which he published in 1922 (see NATURE, Feb. 3, 1923, p 139) In the present note he comments on the inadmissible character of Dr. Crawford's interpretation of certain of the photographs obtained by the latter. In one case the supposed 'teleplastic' structure, which Dr. d'Albe suggests was probably made of chiffon, is shown in the act of partially levitating a small table Crawford supposed that this structure emerging from the medium was pushing the table away from her; whereas Dr. d'Albe shows that the table's centre of gravity is such that the top of the three-cornered piece of chiffon is merely attached to the lower portion of the table top, and is preventing the table from toppling over instead of supporting it.

The weather during August in Great Britain and Ireland was noteworthy on account of the excessive rainfall in all districts excepting northern Scotland, especially in the Orkneys and Shetlands, where Lerwick had less than half the normal total for August. There were two fine periods—one near the beginning of the month and the other at the end. Rain, however, occurred on most days, and thunderstorms were numerous and widespread. At many places rain fell on more than 20 days; London had 7 days free from rain and Dublin only 4. Exceptional rainfalls were recorded in many districts, particularly from Aug. 5 to Aug. 12, 3.47 in. being recorded at Glen Lyon (Invermearan) on Aug 5, and 2 21 in. at Marchmont on Aug. 8. In Perthshire and the Lothians the rainstorms were of unusual intensity on Aug. 8 and 9. In Edinburgh the month was the wettest August since 1770, with the exception perhaps of the years 1829 and 1877 In parts of northern and north-western England and Wales, monthly rainfall totals exceeded more than twice the normal. Harrogate with 7.5 in., and Ilkley with 82 in., had nearly three times the normal. The week ending Aug. 20 was the wettest in most districts, and the total general rainfall in the Midland counties of England was nearly four times the normal during this period. In some parts of Northern Ireland there was a deficiency of rainfall, but at Mallarany 2.14 m. fell on Aug. 6 and 273 on Aug. 14. Expressed as a percentage of the normal August rainfall for the period 1881-1915, the monthly total this year for England and Wales was 155 per cent., while that for the year 1917 was 210 per cent., and for 1912, 216 per cent. It will be seen, therefore, that in the years 1912 and 1917 August was even wetter than it was this year.

England, or that part of it lying to the south of a line joining the Bristol Channel to the Wash, experienced a period of recurring rains from Sept. 13-15. The rains were caused by two depressions, one moving south-eastwards from Ireland on Sept. 13 and the other eastwards up the English Channel a day later. The largest daily total of rain occurred between the mornings of Sept. 14 and 15. During this period Brighton had 2.52 in.; Southsea, 2.41 m.;

Norwich, 2 26 m; Winchester, 2 21 m, Southampton, 201 m; Littlehampton, 197 m., Marlborough, 190 m; Bognor, 189 m, Yaimouth, 182 m; Leafield and South Farnborough, 1.73 m.; Ventnor, 169 in; Hellingly, 166 in, Worthing and Bath, 165 m.; Bournemouth and Weymouth, 161 in. In the area considered, with the exception of a small narrow strip near the south-east coast, the day totals were well above an inch in most The intensity of the rainfall during the three rain days, Sept. 13, 14, 15, becomes more apparent when the totals for the three days are taken (the normal for the whole month of September for the period 1881-1915 is given in brackets after each station mentioned); Norwich, 384 in (214 in), Yarmouth, 3 73 in (1.96 in.), Marlborough, 3 15 in (2·10 m); Brighton, 3 08 m. (2·05 m.); Southsea, 265 m. (217 m.), Bognor, 260 in. (207 m.); Lowestoft, 2 55 m. (1 96 m). Many other places had 15 in.-2.5 in during the period.

THE recent fatal accident at Newport, where a boy was killed when trying to listen to the broadcasting, has created a certain amount of uneasiness among users of radio apparatus. The cause of the accident, however, as shown at the inquest, is fairly obvious. An old piece of badly worn flexible cord was in use for connecting a table lamp to a lampholder by means of an adaptor. The flexible cord was wound round the knobs of two of the bedposts, and both the bedstead and the metal of the portable lamp were 'alive.' A bad shock, therefore, would be obtained by touching the metal of the bedstead and anything connected with the earth, for example, a damp wall, a metal beam, or a gas fitting. The boy had put one of the wires connected with his crystal radio set into his mouth under the impression that this would make him hear better. This wire was, as usual, connected with the earth, consequently, if he touched either the metal bedstead or the lamp he would receive a tremendous shock, which would almost certainly be fatal. Apparently the electric lighting had been installed in an unsatisfactory way. but this had little to do with the accident, which was due to the defective flexible cord The accident has very little connexion with broadcasting receiving sets. It proves, however, the necessity of care being exercised when a receiving set is connected with the lighting mains. To get a shock it is necessary for the lighting circuit to be defectively installed and for the individual to be making good contact with the earth, standing, for example, with damp boots on a damp floor. Flexible cord for a reading lamp is often in contact with a metal bedstead. If the cord be defective the metal may become alive and serious shocks will be obtained if any one touches it and anything connected with earth; the less the resistance to earth the greater the shock. a state of affairs should always be remedical at once.

Using an antenna only 25 feet long which emitted waves having a frequency of 9140 kilocycles (32.8

metres), an experimental radio station in America has been heard all over the world. It has been picked up and rebroadcast in Australia. These high frequency waves have the peculiarity that they seem to skip over long distances and then for greater distances become clearly audible again. We learn from a Daily News Bulletin issued by Science Service, of Washington, that the engineers of the General Electric Co at Schenectady, when experimenting with waves having a frequency of 60,000 kilocycles (5 metres), have discovered new and interesting phenomena The preliminary tests made showed that these signals produced a shadow effect very similar to that produced by light. A small hill, for example, prevented reception in the valley beyond, although the transmitting set was fifty feet above the level of the ground. Using a power of only 60 watts, which is the power taken by an ordinary electric lamp, it was possible to pick up the signals 32 miles away. All the tests were made in the day time, but further tests with higher powers at night time are being carried out. A receiving set for these waves is being placed on the top of the Woolworth Building in New York City, which is 135 miles away. This building was selected because there is an uninterrupted line of 'vision' between it and the Schenectady sending set The region of the spectrum between these rays and the invisible heat and infra red rays has still to be explored.

THE success of broadcasting has led many to speculate on the possibilities of other applications of Hertzian waves Broadcasting appears to be the culmination of the development of the non-directional property of these waves. Developing the possibilities of directional transmission is attracting a great deal of attention at the present time. Dr. Dellinger, in an address printed in the Journal of the Franklin Institute for August of this year, makes some interesting suggestions. A fair amount of success has been attained in concentrating a beam of radio waves in one direction. With short waves, beams have been transmitted thousands of miles. These waves exhibit the phenomenon known as 'skip-distance,' that is, beyond a short distance round the transmitting station, there may be a zone of several hundred miles where the signal cannot be received. Beyond this there is a zone of a definite width where the signals can be heard quite clearly. If it were possible, therefore, to confine such waves sharply along a given line from the transmitting station, there would only be a limited area on which the signals from the transmitting station could be received. By controlling the frequency and the direction it would thus be possible theoretically to communicate exclusively with one definite locality on the earth's surface. At present this is impossible, as the beam is not sufficiently concentrated. Dr. Dellinger thinks that the idea of transmitting substantial amounts of power by radio is quite Utopian. Engineers doubtless could build a radio station which could transmit enough power to light and heat a house several miles away, but the commercial efficiency would be hopelessly low. Directive radio has proved of great value in aviation and in navigation. It appears to have a great future for these purposes. It has not been very successful so far for individual communication, and it probably will never be successful for power transmission

AT the annual conference of the National Veterinary Medical Association, held at Torquay last week, tuberculosis was the subject of an important discussion. Major B. de Vine, of the Birmingham Veterinary Department, pointed out that large sums are being expended annually upon sanatoria, hospitals, and clinics for the treatment of human tuberculosis. These costly measures might soon become unnecessary if legislation provided powers to deal with the disease in cattle during its early stages. Prof. Hobday, Principal of the Royal Veterinary College, said that although human pulmonary tuberculosis is becoming less and less prevalent, much abdominal tuberculosis, particularly in children, remains, and is always derived from tuberculous infected milk If, therefore, cattle could be freed from the disease, the lives of 10,000 children who die yearly of the infection might be saved. He alluded to the work of Calmette and Guerin in France, who have prepared an attenuated living culture of the tubercle bacillus as a preventive vaccine against the disease, which has been used experimentally on calves with wonderful success, and to the work of Dr. Nathan Raw in Great Britain, who is carrying out a similar method with a dead vaccine. If these measures were equally successful when applied to man, human tuberculosis might well become a thing of the past. Both Prof. Hobday and Prof. Wooldridge emphasised the importance of medical men and veterinary surgeons working in collaboration for the general good.

The third annual Norman Lockyer lecture of the British Science Guild will be given by the Very Rev. Dean Inge on Monday afternoon, Nov. 21, in the Goldsmiths' Hall, London.

THE seventy-second annual exhibition of the Royal Photographic Society of Great Britain was opened on Sept. 12, at 35 Russell Square, W.C.1, and will continue open until Oct. 8. Admission is free. The exhibition includes this year, in addition to more than one thousand selected photographs of various subjects, many of them of great beauty and interest, a number of pieces of historic and modern scientific apparatus and photographic accessories. Different sections of the exhibition are devoted to natura, history, photomicrography, radiography, astronomical and aerial photography, and technical applications, including meteorological, geological, and metallurgical photography and useful photographic devices. A special number of the Photographic Journal (price 1s. 9d, post free) contains authoritative articles on different sections of the exhibition and many reproductions of pictures, including twenty from the natural history section.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A demonstrator in mathematics in the Royal College of Science —The Secretary, Imperial College of Science and Technology, South Kensington, S.W.7 (Sept. 27). An open research fellowship in the department of Coal Gas and Fuel Industries of Leeds University—The Clerk to the Senate, The University, Leeds (Sept. 30). A lecturer in dental anatomy (including comparative anatomy), physiology, and histology at the Dental School, Cairo—The Director of the Dental School,

Cairo (Sept. 30). A second demonstrator (medically qualified) for the department of physiology—The School Secretary, Middlesex Hospital Medical School, Mortimer Street, W.1 (Oct. 8). An assistant master to teach biology—The Secretary, City of London School, Victoria Embankment, E.C 4 (Oct. 10). A biologist at the Dove Marine Laboratory, Cullercoats—The Registrar, Armstrong College, Newcastle-upon-Tyne (Oct. 13). A district lecturer in agriculture and an assistant lecturer in dairy husbandry in the University of Leeds—The Registrar, The University, Leeds (Oct. 15).

### Our Astronomical Column.

RECENT SUNSPOTS.—The large sunspot, to which attention was directed in Nature of Aug. 27, p. 311, was seen again as it crossed the disc on Sept. 3-16. Although accompanied by a considerable area of bright faculæ, the spot itself had diminished to about one-fifth of the area it presented during its first appearance. It may be noted that the magnetograph traces were somewhat disturbed between Sept. 7 and 15, more particularly on Sept. 9 and 10. On Sept. 10, at  $21\frac{1}{2}$  hr., a wave was recorded by the horizontal force magnetograph at Abinger, Surrey, which represented a change in H.F. of  $250~\gamma$  within 20 minutes. The sunspot already referred to was on the central meridian on Sept. 10.1.

In brief intervals of sunshine on Sept. 14, a naked-eye group was detected near the central meridian. A telescopic view showed a large stream (two large spots with smaller companions between them) which had grown from a few tiny spots photographed near the sun's east limb on Sept. 9. North of this group, another of about half the size was also developing on Sept. 14 and was still increasing when observed again on Sept. 17. These two groups may be looked for at their return to the sun's east limb on Oct. 4 at position angles 135° and 127° respectively from the north point of the image. The larger of these two groups is added to the list of naked-eye spots as follows.

No. Date on Disc. Central Meridian Passage Latitude. Area on Sept. 14. 9 Sept. 9-20 Sept. 14.3 19°S. 1/800 of hemisphere.

The Daylight Fireball of Sept. 7.—Mr. W. F. Denning writes: "This object appears to have attracted a great number of spectators. Some excellent descriptions have been received of its path, direction, and aspect. Observers agree in stating that it pursued a long, horizontal flight from east to west, and that it exhibited a bright bluish-green colour. Reports have come from the south of England, France, and Jersey. The following results have been obtained from a comparison of the observational data:

The radiant point was rising on the eastern horizon and the meteor traversed its extensive course with little change in its height except perhaps near the end of its trajectory, when it apparently exhibited an inclination earthwards."

A SPECTROSCOPIC DETERMINATION OF THE ABERRATION CONSTANT.—In a paper on this subject in *Mon*.

Not. R.A S. for May last, Dr. H Spencer Jones recalls that Sir David Gill's first thought when Mr. Frank McClean offered the Victoria telescope to the Cape Observatory was that it would give a determination of the solar parallax by the annual changes in the radial velocities of the stars. Such a determination was completed in 1908 and gave 8".800±0".006 for the parallax. A new determination has been made from subsequent plates taken between 1908 and 1926. Slightly different values are obtained according to the manner of treating stars with variable radial velocity, but the extreme range is only 0" 003. The adopted result is 8" 800 ± 0" 004 using the same terrestrial radius and velocity of light as in 1908, but on substituting Hayford's spheroid and Michelson's new value of the velocity of light, it becomes  $8^{\prime\prime}\cdot803$ . The corresponding value of the constant of aberration is  $20^{\prime\prime}\cdot475\pm0^{\prime\prime}\cdot010$ . The agreement of the two independent determinations is very satisfactory.

METEOR CRATER, ARIZONA —This remarkable formation, recalling a lunar crater, was formerly known as Coon Butte, and lively discussion took place on its origin; the meteoritic origin was disputed by many experts, including the late Sir Archibald Geikie. Evidence in its favour has, however, accumulated, and it is now so widely accepted in America that the name has been altered to Meteor Crater The Scientific American for September contains an interesting article on it by D Moreau Barringer, junr Some of his principal conclusions are as follows; the amount of rock crushed and displaced was 350,000,000 tons is estimated that this would give a mass of 10,000,000 tons to the falling meteor, if in one piece, this would mean a diameter of 400 feet, but reasons are given for believing it to have come as a swarm of smaller masses. It was at first assumed that the fall was vertical, since the crater is round; it is now thought to have been oblique, and in fact a drill hole on one side of the crater revealed numerous meteoric masses; this search is being continued. The date of the fall is put between 700 and 5000 years ago. A tree growing on the rim of the crater, with some 700 rings, gave the lower limit; the other was fixed by the amount of erosion. The meteors must have been much more concentrated than in the ordinary meteor shower; we may conjecture that it was the actual head of a comet that struck the earth. The small stellar nucleus of Pons Winnecke's comet, seen at its recent approach, suggested considerable concentration, though not so much as in this case.

Meteor Crater has done a good deal to revive the meteoritic theory of the lunar craters; their resemblance is so close that a similar origin in each case is strongly suggested.

THE LIFE-HISTORY OF THE NORTH SEA PLAICE.— The Ministry of Agriculture and Fisheries has recently issued Fisheries Notice, No. 12, which sets out in non-technical language our present knowledge concerning the life-history of the plaice in the North Sea, and of the effect of fishing upon the stock of plaice. Within the compass of an eight-page pamphlet, the author has succeeded in presenting an admirable summary, not only of the known facts, but also of the methods by which the facts have been established. Section 4 deals with the all-important question of the extent to which man takes toll of the quantities of place in the North Sea. The results of marking experiments have shown that out of 1000 living plaice marked and released, 250-300 are recaptured inside a year from the time of marking. It has been estimated, on the basis of all the English marking experiments carried out before the War, that if we start with 1000 male plaice and 1000 female plaice, about  $6-7\frac{1}{2}$  inches long and 2-3 years old, their numbers will decrease in succeeding years as follows:

At the end of the first year, 788 males and 844 females.

,, second ,, 444 ,, ,, 573 ,, ,, third ,, 236 ,, ,, 329 ,, ,, fourth ,, 125 ,, ,, 189 ,,

Thus, at the end of four years, only about one plaice in seven is left. The careful study of market statistics of commercial landings of plaice in the years before and after the War provides an object-lesson on a big scale of how fishing affects the stock of fish. If too many fish are left on the ground owing to there not being enough fishing, the ground gets crowded and the fish do not grow so fast—this actually happened during the War. So, too, when a new ground is fished for the first time, the fish caught are generally large and thin and old; but as this old accumulated stock is reduced by fishing, the survivors begin to thrive and grow faster, so that fishing improves the growth-rate of the individual fish. But if the fishery is continued on too big a scale, the fish, fast-growing though they may be, do not grow up in sufficient numbers, with the result that the medium and large fish becomes very scarce.

Freshwater Eels in the Pacific Area.—In order to complete his well-known work on the distribution and biology of the freshwater eels, Dr. Johs. Schmidt last year undertook a voyage to the Pacific to study the tropical species in their native habitat. In an article entitled "Les Anguilles de Tahiti" (La Nature, No. 2765, July 15) he gives a résumé of his investigations, and the new methods he has employed in the identification of species, illustrated by excellent diagrams and photographs. Tahiti was chosen as a centre largely because Darwin's account of the island in his "Journal of a Naturalist during a Voyage round the World in H.M.S. Beagle," showed its suitability for the purpose, and also because the three species of eels which occur there in great abundance are widely distributed in the tropical Pacific. The species are found in very different conditions, their colour harmonising with their surroundings. Anguilla obscura, dark and unspotted, lives in the mud and stagnant waters of shallow ponds; the spotted A. megastoma and A. mauritiana, both of which attain a great size, are found on the pebble and gravel beds of the rivers, the first in the rapid streams of the mountain districts and the other in the rivers nearer the Dr. Schmidt refers to the numerous native legends connected with the eel, and especially to the story of a giant race of eared eels peculiar to Lake

Vaihiria, to which his attention was first directed by Sir John Murray. This legend has proved easy of explanation. The so-called 'ears' have nothing to do with the auditory organs, but are simply the two pectoral fins just behind the head, one on each side, small and not easily seen in the young animal, but deeply coloured and very noticeable in the adult. The two specimens collected in Lake Vaihiria by the Challenger Expedition, and now in the British Museum, were examined, and proved to be nothing more than very large examples of A. megastoma and A mauritiana. With regard to the migrations of the Pacific eels, Dr. Schmidt states that it is not possible to determine their breeding-places with any exactitude unless a research vessel equipped for the purpose is employed. He was able, however, to make a series of observations on one of the species, A. mauritiana, from which he concludes that this species at least differs very greatly from the European eel in its breeding habits, and that it forms two distinct races, each with a different centre of reproduction.

Damage by Marine Crustaceans.—A fresh example of serious damage done to submarine timbers by crustaceans has been described by Dr. James Ritchie (Scottish Naturalist, 1927, p. 37). Dock-gates of yellow pine and greenheart were placed in Methil Docks, on the Firth of Forth, in 1897, and by the autumn of 1925 they had become so dilapidated that they were removed and replaced by dock-gates of steel. The damage was entirely due to the boring of Limnonia lignorum and Chelura terebrans, small isopod and amphipod crustaceans. Of these, Chelura was the most numerous and most serious pest, and in typical portions of the damaged timbers it had caused the removal of as much as 13 inches of wood, the rate of damage averaging more than one-third of an inch a year. Chelura has not hitherto been found in the Forth estuary, although in association with Limnoria it has a world-wide distribution, and the suggestion is made that its presence at Methil may be due to a relatively recent importation in timber from another port, and that there is a possibility of a colonisation of the Firth of Forth from the Methil centre by this destructive pest.

NORTHERN CTENOPHORA.—Dr. Thilo Krumbach, in describing the Ctenophora of the North Sea and Baltic ("Die Tierwelt der Nord- und Ostsee," Lieferung 7, Teil 3, f 1. Leipzig: Academische Verlagsgesellschaft m.b.H., 1927), gives a very able account of the group, emphasising the general biology although in no wise neglecting the morphology. Ctenophores have now a peculiar significance as they are known to be such carnivorous feeders that they must be regarded as serious enemies to young fishes, both directly by eating them and indirectly by swallowing in huge quantities the food which the fishes themselves might have eaten. They are thus not only interesting in themselves, but also must be taken into account by all fisheries workers. Beroe alone may be regarded as a friend as it devours other etenophores. The author only allows three species in the area covered :-Pleurobrachia pileus, Bolinopsis infundibulum, and Beroë cucumis, all well known; occasional so-called closely related species recorded by other zoologists being included in these. As visitors he records Mertensia ovum from the Arctic regions and Cestum veneris from the warmer seas. This arrangement is satisfactory and simple, for it seems right to bring together such evidently closely related forms which,

for example, are described as separate species from the Mediterranean and the present area. *Bolinopsis* infundibulum and *B. hydatina* are thus regarded as synonymous, an arrangement with which we heartily agree, as the chief difference is in the windings of the lobe canals, which certainly in the British form can vary to a large extent according to age

MARINE PLANKTON IN RELATION TO PHYSICAL AND CHEMICAL FACTORS.—Miss S M. Maishall and Mr. A. P. Orr, working from the Marine Station, Millport, have made a careful and elaborate study of plankton production in the Clyde area, and particularly in Loch Striven, which was visited weekly for the greater part of 1926. The results are given in Jour. Marine Biol. Assoc., 14, 4, May 1927, pp. 837-868 Simultaneous observations were made on the quantity and character of the plankton, dissolved oxygen saturation, phosphates, salinity, pH, nitrates, and nitrites, meteorological conditions were also taken into account. close relation was found to exist, at least for the surface layers, between the quantity of diatoms and the changes in pH, dissolved oxygen and phosphates. The usual spring maximum of diatoms occurs, but there are others later in the year, more numerous than in the open sea, due apparently to the more frequent mixing of the water in the Loch. The conditions leading up to the spring maximum are discussed, and the conclusion reached that neither amount of sunlight nor rise of temperature is the decisive factor. paper contains much valuable data, and is well illustrated by some twenty graphs; it is important particularly in relation to the work of Atkins in England and Gran in Norway.

TEST FOR INCIPIENT PUTREFACTION OF MEAT.-Fresh meat is such an important article of diet that some rapid test that would indicate whether butcher's meat is strictly fresh or otherwise is very desirable, and many investigations have been made in order to devise one. Mr. Ralph H. Weaver has recently published the results of investigations into this question (Technical Bull., No 79, Agricultural Experiment Station, Michigan State College) Fresh Hamburger steak was employed, and Mr. Weaver finds that neither the number nor the characters of the micro-organisms present prove a sure guide. Finally, a test was devised which has given promising results. One gram of the meat is placed in a test-tube with 10 c.c. of a standard meat broth. A strip of lead acetate paper is suspended in the tube, which is then incubated in a partial vacuum at 37° C. and the time of appearance of blackening of the acetate paper, indicating the presence of hydrogen sulphide, is noted. Good meat gave a positive result in 7-10 hours, stale meat in 2-5 hours.

Cretaceous Mollusca from Japan.—A narrow belt of Cretaceous beds, known as the Sanchû Graben, occurs faulted down between Palæzoic rocks in the main island of Japan to the north-west of Tokyo. These beds, representing several stages of the Lower Cretaceous, have been subdivided into five groups, and a recent paper by H. Yabe, T. Nagao, and S. Shimizu deals with the fossil Mollusca of the upper three (Science Repts., Tôhoku Imp. Univ., Sendai, Ser. 2, vol. 9, No. 2). Eleven species of Ammonites, six of Gastropoda, and twenty-eight species with two varieties of Pelecypoda are described, a large number as new, and well illustrated.

The Geology of St. Helena.—The full report of Prof. R. A. Daly's recent investigation of St. Helena has now been published in the *Proc. Amer. Acad. Arts and Sci.*, vol. 62 (2), 1927, and is a geological document of great importance and interest, adding as it does to

our still meagre knowledge of the deep-sea islands. The emerged part of the island is a composite volcanic structure made up of two domes, each of which has been built up by lavas from a network of fissures larger dome has been punctured by a dozen pipes of phonolite and alkali-trachyte. Basalt is otherwise by far the commonest rock. Unlike Ascension, St. Helena provides no evidence of a continental type of foundation. From the point of view of isostasy the island is remarkable, for despite the fact that it appears to be largely uncompensated and therefore represents a heavy load carried by the earth's crust, it shows no sign of having subsided during a period of the order of a million years. Stability in recent times is proved by the presence of the five-metre wave-cut bench which here, and in many other parts of the world, indicates a eustatic fall of sea-level that probably took place some three thousand years ago. No new facts bearing on the age of the island have been discovered, but the geological history is in accordance with Wallace's deduction from the fauna and flora that the island dates back to at least the Miocene.

THE ORIGIN OF ANORTHOSITE.—A noteworthy contribution to the evidence bearing on the still unsolved problem of the origin of anorthosites is made by J. B. Mawdsley in his report on the St. Urbain area of Quebec (Mem. Geol Survey Canada, 152, 1927). The mass described has a smoothly ovoid form against a series of granites and diorites The latter overlie the series of granites and diorites anorthosite complex and in places hold blocks of basic anorthosite. Within the anorthosite body itself more albitic phases cut and enclose blocks of an earlier and more anorthitic phase. All the rocks contain fragments of large andesine crystals, suggesting that the granite-diorite series and the anorthosites are closely related. Foliation in both series, in a narrow zone following the main contact, further suggests relative movement between them while each was still in a condition in which flowage was possible. Mr. Mawdsley suggests that this puzzling association implies that at least the later andesine-anorthosite advanced into its present position as a liquid This conclusion is at variance with the well-known hypothesis due to Bowen, according to which anorthosites have been formed in situ by the collection of felspar crystals from a gabbroid magma, and not from a magma of their own composition. If sound in principle, as it appears to be, Bowen's views must be modified to allow for subsequent flowage of the crystal aggregate on a scale, and with an ease of movement, not previously thought to be necessary.

THE EVAPORATION OF WATER.—Volume 4 of the Japanese Journal of Astronomy and Geophysics contains a contribution on this subject by Mr. T. Hirata of the Forestry Experimental Station. His evaporimeter was a polished copper pot 20 cm. in diameter and 10 cm. deep filled with water to a depth of 2 cm. and placed on a sodded mound 20 cm. high. The height of the water was observed each day at 10 A.M. (This appears to be the usual instrument of the Japanese meteorological service.) The observations are consistent with the relation :-- depth of water evaporated =  $a(V - v)\sqrt{W}$  where a is a constant, V the saturation vapour pressure at the temperature of the surface water, v the actual vapour pressure in the arrabove, and W is the velocity of the wind over the surface. The value of a depends on the amount of sunshine and the heat conducted to the pot by its surroundings. It is reduced by an increase in the size of the pot. The effect of sunshine dimmishes with altitude of the surface above sea-level up to 700 metres and then becomes nearly independent of altıtude.

LIGHTING IN FACTORIES.—In the Journal of the National Institute of Industrial Psychology (vol. 3, No. 7) is an article on lighting in the factory by Mr. A M. Hudson He maintains that although improvements in lighting have been made in recent years, yet many factories still fail to make the best use of daylight, and that artificial lighting is generally below the standards that modern research has shown to be physiologically desirable. He discusses the effect of dirty windows—unfortunately far too common—the relation of under illumination and eyestrain, the effects of inadequate artificial light in reducing output and increasing strain. He points out the importance of a study of glare, concerning which there is much work to be done. He pleads for a much greater use of photometers in factories, particularly in fine-process and inspection depart-The subject is one of extreme importance, and it seems clear that while there is room for much more scientific work on the problems of lighting, there is also room for a wider application of what is already

ACTIVE NITROGEN.—The August number of the Physical Review contains several papers on active nitrogen. In one, P. A. Constantinides has described experiments performed by him under the direction of Prof. Dempster, from which he concludes that it is not ionised, and suggests that its essential constituent is an excited diatomic nitrogen molecule, with an energy of activation equivalent to about ten volts. In a second communication, E. O. Hulburt and W. H. Crew state, inter alia, that active nitrogen can be formed under conditions in which it is unlikely that there is any considerable dissociation into atoms, whilst in two further papers, Prof. Mulliken and some collaborators have given a detailed analysis of the  $\beta$  bands of nitric oxide. These were produced in the nitrogen afterglow, and photographed in the second order of a 21-ft. Rowland concave grating. The mass of information which they have obtained is important both for the light which it throws on the structure of nitric oxide, and also for the test which it affords of theoretical predictions about the nature and probability of the various quantum transitions which occur in diatomic molecules.

CHROMIUM - PLATING. — The Chemiker - Zeitung of Aug. 10 contains an account of recent developments in the art of chromium-plating, which has hitherto been attended with serious difficulties. Not only has it been possible, by the use of suitable electrolytes, to reduce both the quantity and the density of the current to reasonable dimensions, but also the disturbing effect of the hydrogen evolved at the cathode has been recently eliminated, without the application of heat, by a new process patented by Dr. von Bosse. It has been ascertained that the amount of hydrogen occluded by the chromium increases very considerably with increasing current-density and frequently cracking and scaling of the deposit takes place. The chromium-hydrogen alloy thus produced can, however, be broken down by the application of a hightension alternating current in a highly evacuated chamber, when light is emitted and in the course of a few minutes the hydrogen is completely eliminated as gas The end of the process can be recognised by observing the change which takes place in the character of the light emitted. The necessary apparatus is supplied by the firm Langbein-Pfanhauser of Leipzig and Vienna.

Adsorption on Charcoal.—Interesting experiments on the adsorption of acids from solution by ash-free charcoal are described by E. J. Miller and S.

L. Bandemer in the July number of the Journal of the American Chemical Society. The results show that acids adsorbed on charcoal are incapable of inverting sucrose in solution. It is suggested that the adsorbed acids are in an undissociated state, that (contrary to existing ideas) the adsorption of acids does not imply a high concentration of hydrogen ions around the adsorbent, and that some theories of adsorption and catalysis are seriously affected by the results.

THE ATOMIC WEIGHT OF SCANDIUM.—N. H. Smith describes experiments in the July number of the Journal of the American Chemical Society on the atomic weight of scandium. Anhydrous scandium chloride (ScCl3) was prepared by the action of pure carbon tetrachloride on the oxide at 750°-800°. The material used was pure, and the corrections necessary in Honigschmid's previous determinations, made in 1919 with scandium bromide contaminated with small quantities of scandium oxide formed by the action of the bromide on quartz apparatus, were avoided. A solution of the chloride was almost exactly precipitated with silver nitrate solution from a weighed amount of pure silver, and the slight excess of halogen or silver determined by the nephelometer. The atomic weights of chlorine and silver were assumed as  $35\,457$  and  $107\,880$ , and the average of nine analyses gave Sc = 45 160, in fair agreement with Honigschmid's value 45 099 (earlier values ranged from 43 90 to 45 23). The origin of the materia. used by Smith is not stated.

THE CONSTITUTION OF THE PROTEINS —The behaviour of protoplasm seems very closely bound up with the physical and chemical properties of the proteins, of which protoplasm is largely composed; and some elucidation of the chemical structure of the protein molecule will go far towards clearing up some of the problems underlying the metabolic activities of living cells The mechanism of heredity depending, so far as we can judge, on the specificity of living matter, may possibly also be in some measure explained by structural variations displayed by the proteins. The polypeptide theory of the constitution of the proteins, propounded by Emil Fischer, has long held the field. He conceived proteins as gigantic molecules consisting essentially of several amino acids joined together by means of the peptide linkage —CO—NH—, thus forming a considerably long chain. In Acta Phytochimica (vol. 2, No. 4, Dec. 1926) Prof. Keita Shibata, of the Imperial University of Tokyo, supports the view that the molecules of amino acid anhydrides, which are mostly derivatives of diketopiperazines, are bound together by a force other than ordinary valency, giving rise to a colloidmicell of definite magnitude, the protein molecule. Apparently this new idea suggested itself to investigators through analogy to the now prevalent and well-founded conception of the constitution of the polysaccharides, such as starch, cellulose, glycogen, inulin, which may be regarded as association or polymerisation products of the ground bodies, i.e. anhydrides of simple The theory of the anhydridic structure of protein is now receiving support from various sides. Some of the outstanding evidence from recent experimental work include: (a) Its characteristic colour reaction towards soda-alkaline solution of picric acid (Abderhalden); (b) its oxidation and reduction products (Abderhalden); (c) its rontgenographic properties and the determinations of its molecular weight (Herzog, Troensegaard); (d) the action of hypobromite on it (Goldschmidt); and (e) its racemisation in alkaline media (Levene).

# The Morphology of the Insect Thorax.

By Dr A. D. Imms, Rothamsted Experimental Station

MUCH has been written relative to the morphology of the insect thorax and its appendages, but few of the contributions of recent years have led to any modification of the present-day conceptions of that subject. The whole problem, however, has been re-investigated in a comprehensive memoir by Dr. R. E Snodgrass, whose work is characterised by clarity of deduction and an honest attempt to place the subject on a better foundation In discussing the general problem of segmentation, he takes us back to the primitive soft-bodied ancestors of the arthropods and points out that in such animals the grooves limiting the body-segments coincided with the lines of attachments of the longitudinal muscles. This same condition is still met with in many insect larvæ. Adult arthropods, on the other hand, with their hard exoskeletal body-plates, have acquired a secondary segmentation. This has been achieved by the development of a membranous unchitinised zone just in front of each muscle-bearing intersegmental groove. The function of this flexible area is to admit of freedom of movement and telescoping of the hardened resistent segments. Such membranous areas are commonly regarded as truly intersegmental in position, but, as Janet was the first to demonstrate, the term intersegmental membrane, although justified from its function, is morphologically inexact. Flexibility could not well be at the original intersegmental grooves because the muscles are here attached and demand firm support. The dorsal and ventral regions of these grooves have become converted into internal ridges, which have become fused with the skeletal plates immediately behind them as is shown in the accompanying illustration (Fig. 1).

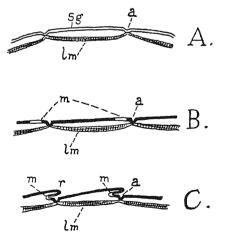

FIG. 1.—Diagram of lengthwise section of portion of a segmented animal (adapted from Snodgrass).

- A. Primary segmentation of soft-bodied animal with segments marked by intersegmental grooves.
   B. Secondary segmentation of an insect with chitinised body-wall and membrane developed in front of the primitive intersegmental
- C. Secondary segmentation accompanied by telescoping of the segments, each segmental plate ending in a posterior icduplication.
  a, primitive intersegmental groove; lm, longitudinal segmental muscle; m, membrane; r, reduplication; sy, segment.

In discussing the morphology of the primitive arthropod limb, Dr. Snodgrass takes as his starting-

<sup>1</sup> Smithsonian Miscellaneous Collections, vol. 80, No. 1. Morphology and Mechanism of the Insect Thorax. By R. E. Snodgrass (Publication 2915.) Pp. 108 (Washington, D.C.: Smithsonian Institution.)

point the hypothetical generalised appendage, which rami—the exopodite and the endopodite Of the three segments into which the protopodite is divided. the first (pleuropodite or subcoxa), he maintains, has lost its power of movement in insects evolving limb came to demand more rigid support, the subcoxa became flattened out and embedded in the wall of its segment as the forerunner of the pleuron. The coxa (coxopodite) was thus forced to replace the subcoxa as the functional base of the lmb m all msects. The hypothetical biramous appendage does not, unquestionably, appear to have been retained in any insect. The only fact that can be construed as evidence of this feature, is the presence of styli on the coxe of the middle and hind legs of Machilis and related genera. It is claimed by many morphologists that these styli are exopodites, whereas a true exopodite is borne on the basipoditoa segment either lacking in most insects or included in the trochanter. Dr. Snodgrass maintains that it still remains to be demonstrated that these organs are other than merely secondary structures. His discussion of the hypothetical evolution of the pleuron is too lengthy to be detailed here, but, in a few words, it may be said that according to the view upheld in his memoir, the original subcoxa became reduced to a basal eupleuron, from which the epimeron and episternum were later derived, and a distal trochantin in immediate contact with the coxa.

With regard to the leg-segments, reference is made to the double trochanter so frequent in the parasitic Hymenoptera. The proximal segment of this region, Dr. Snodgrass believes, is the true trochanter, and he bases this conclusion on a study of the reductor femoris musele. The second trochanter is merely a basal area of the femur, separated off from the main portion of that segment by means of a secondary suture and ridge In the nymphs and adults of the Odonata the structural relations of the double trochanter appear to be quite different, and Dr. Snodgrass brings forward evidence for concluding that, in this order of insects, the two trochanters represent two primary leg segments, as has already been maintained by Verhoeff. In most insects the two trochanteral segments have fused into a single piece

With regard to the tarsus, this region consists of a single segment in holometabolous larvæ as it does in adult Protura, which segment is to be regarded as the propodite of the generalised arthropod limb. In most insects the tarsi are divided usually into five subsegments, and these latter appear to be subdivisions of the single primitive shaft. They have no articular hinges with each other and are never provided with their own special muscles-facts which evidence that these divisions are not true segments. The tarsus is moved, as a whole, by muscles inserted into its base, or by tension of the claw muscles on the tendon which traverses it. The region at the extremity of the tarsus—the 'foot' in usual terminology—consists of a group of organs which were designated the prætarsus by de Meijere. In its simplest form it consists of a median claw-like segment · in this form it occurs in the Protura, in certain Collembola, in caterpillars, sawfly larvæ, and in most beetle larvæ.

Dr. Snodgrass follows de Meijere and regards the prætarsus not as an outgrowth of the last tarsal 'segment,' but as a development of the dactylopodite

No. 3021, Vol. 1201

of the generalised arthropod limb. In the Lepismidæ each prætarsus bears three claws and it appears probable that the smaller median claw is the homologue of the original dactylopodite and that the lateral claws of these, and most other adult insects, are subsequent developments. According to de Meijere, the paired claws are outgrowths from the base of the original dactylopodite. One or other of these, on

the other hand, may be secondarily suppressed, as in many of the Anoplura (sensu lat).

In addition to those features already alluded to, this memoir discusses the tergal and sternal sclerites, the origin of wings, the flight muscles, position of the spiracles, etc. These and sundry other problems must be left to the reader who desires to consult this suggestive work first hand.

# Forestry Research in South Africa.

THE research work which is being carried out by Dr. John Phillips at the Forest Research Station, Deepwalls, Knysna, in South Africa, is of considerable interest to practical foresters, whilst at the same time being of botanical value. Dr. Phillips graduated B Sc in forestry in 1922, and his work in South Africa has recently received the recognition of the degree of D.Sc. from the University of Edinburgh. Two recent papers published in the South African Journal of Science for December last, indicate the lines upon which Dr. Phillips is working.

The first deals with the ecology and sylviculture of the monotypic genus Virgilia Lamk, an important tree of seral forest at the Knysna. The tree is said to be of use in sylviculture, affording excellent cover to the seedlings of other forest species. It is readily raised from seed and transplants easily. The Virgilia is one of the fastest-growing native trees at the Knysna, natural stands often requiring thinning. In spite of these important faculties its distribution is restricted, as is that of others of the curious indigenous species of these South African forests. The species is light-demanding, developing best on soils of medium hollard, being susceptible to frost, but capable of resisting high surface-soil temperatures in its seedling stages, a characteristic of considerable importance.

After dealing with the botanical characters of Virgilia, the author discusses the subject of its restricted range. Schonland considered it to be a relict; to this the author agrees, "if 'relict' implies that the species is an old but not an effete one." The study of the species has shown that it is a virile one, but owing to its poor means of dispersal, must have taken a considerable time to extend its limits. Dr. Phillips expresses the view that the species, being evolved within the south-western region, and dependent upon a medium hollard and the absence of frost, has been unable to invade areas surrounding that region. Poor means of dispersal, need of the seed to be stimulated before it will germinate, and dependence upon a particular strain of Pseudomonus radicicola are other factors to which he ascribes the restricted range.

Elsewhere in the same journal Dr. Phillips deals with the propagation of 'stinkwood' (Ocotea bullata E. Meyer) by vegetative means. So early as the seventies of last century Captain C. Harison, first Conservator of Forests of the Knysna-Humansdorp Forests, endeavoured to propagate this species by cuttings. The attempt was unsuccessful. In 1882 the Comte de Vasselo de Regne, Superintendent of Woods and Forests, considered that the stinkwood could reproduce itself like the poplar by cuttings, and recommended that experiments should be undertaken on the lines he recommended. These efforts were also unsuccessful, as were those of D. E. Hutchins, Conservator of Forests from 1888 until 1892. Other attempts carried out by forest officers from that date to 1922 proved abortive.

to 1922 proved abortive.

The experiments detailed in the present paper were commenced in the latter year, and so far as the work has gone to the present date, Dr. Phillips is forced to the conclusion that the propagation of the Ocotea

by vegetative means is not possible on a practical scale; but he invites criticism and suggestions from fellow-workers in this field of research. The continued experimentation under controlled conditions has shown that Ocotea bullata can be made to form callus and roots from cuttings, leaves, eyes, root-cuttings, and layers, but that the percentage of success obtained is insignificant. Furthermore, it is clear that establishment of the callussed and rooted portions is a matter of great difficulty. The principle reasons for the poor response of the plant are to be found in the delicate nature of the shoots and in the occurrence of the strongly lignified stereome and the U-shaped stone cells in the pericycle.

The practical value of the research work here undertaken will be obvious to the forest officer; for the effort to propagate the species has been until lately the subject of more or less rough experiments carried out for more than half a century

In a third paper published in the same journal, Dr Phillips gives a summary of pieliminary studies on the general biology of the flowers, figures, and young regeneration of sixty-three of the more important trees and shrubs occurring in the Knysna forest. This little handbook should prove of the greatest value to forest officers both from the botanical point of view and that of the sylvicultural. In support of the latter the following may be quoted:

"A point of the very greatest interest, but not at all easy to explain, is the truly excellent manner in which the yellow-wood (Podecarpus Thumbergii Hook) regenerates. . . . It might be suggested that the Knysna forests were in the past ages pure Podecarpus communities, and that these Gymnosperms are being slowly ousted by Phanerogamic trees; this supposition, however, is certainly not supported by the present efficient manner in which P. Thumbergii (and in places P elongata L'Herit, as well) regenerates. Perhaps the regeneration process, though still so excellent, has, with the centuries, gradually decreased in efficiency, and possibly the incoming hordes of flowering trees and shrubs are slowly but surely gaining the upper hand."

The author deals with the botanical characteristics of the sixty-three species on the usual lines. He then summarises the dispersal of the fruits and seeds under the headings of wind, water, birds, mammals, man, and 'various,' and discusses generally the question of dispersal—an important matter from the forestry point of view. In one of his tables Dr. Phillips summarises information relating to viability, chief agents of mortality, and average period required for germination of seeds. The author's results were based on "phenological studies of definitely marked trees over a period of about three and a half years, study of the structure of fruits and flowers, pollination experiments under natural and under controlled conditions, observations and experiments connected with the dispersal of fruits and seeds, and nursery

and quadrate germination experiments.

These papers place Dr. Phillips in the forefront amongst the younger generation of workers in this type of research work.

# University and Educational Intelligence.

Bristol.—The new Henry Herbert Wills Physics Laboratory, now practically completed, will be opened by Sir Ernest Rutherford on Oct 21. At the conclusion of the ceremony and inspection of the Laboratory, a Degree Congregation will be held at which the degree of Doctor of Science honoris causa will be conferred upon the following. Prof. Max Born (Gottingen), Sir William Bragg (Royal Institution, London), Prof. A. S. Eddington (Cambridge), Prot. Alfred Fowler (Imperial College of Science and Technology, London), Prof. P. Langevin (Paris), and Sir Ernest Rutherford (Cambridge)

DURHAM.—Mr. R B. Green, lecturer in anatomy at the College of Medicine, Newcastle-on-Tyne, for the past five years, and author of a "Manual of Human Anatomy for Dental Students," has been elected professor of anatomy in succession to Prof. R. Howden.

THE Department of the Interior, Bureau of Education, U.S.Ā, has issued a report (Bull, 1927, No. 14) on "Physical Education in American Colleges and Universities," by Marie M. Ready. The information has been collected from 182 institutions. Of these, 129 require a medical examination at entrance, 65 include physical efficiency tests as a part of it, and 79 keep continuous records of the students' physical condition during their entire college course. Corrective gymnastics are prescribed and required of those needing them by 70 per cent. of the institutions. Ability to pass certain tests in swimming is required by 48 institutions for graduation. A large number of institutions require a certain amount of physical education as a part of every undergraduate course leading to graduation; courses on hygiene are also required by many. Vaccination for small pox is made a definite requirement by 58, and for typhoid fever by 13 institutions.

THE Pan-Pacific Conference of Education, Rehabilitation, Reclamation, and Recreation, held at Honolulu last April, has a certain significance as a new grouping for purposes of international intellectual co-operation. The conference was called by the President of the United States and presided over by the U.S. Secretary of the Interior The other countries represented were Great Britam, Australia, Fiji Islands and British Western Pacific, New Zealand, France, Japan, Chile. Peru, Mexico, Colombia, and Nicaragua. The more important of the discussions were those on education, and these led up to a series of important resolutions, among which were the following: It is desirable to promote interchange of educational ideas and the establishment of educational centres of information through such means as visits of eminent professors, creation of university information bureaux. uniformity in educational terminology, and, as a step to that end, publication by the Bureau of Education, Washington, of a glossary of current educational terms, appointment of educational attachés to embassies and legations, and of a government Pan-Pacific committee on museum co-operation; vocational education of less than college grade should be included in the public school programme for the benefit of those who do not go to college; the extension of parental education by means of health centres, visiting nurses, correspondence courses, etc., should be encouraged, systematic co-ordination of the home with the school programme should be effected, and courses in maternal and child hygiene should be introduced so far as possible into the curriculum of secondary schools. A summary report of the proceedings appears in School Life (Bureau of Education, Washington) for June 1927.

# Calendar of Discovery and Invention.

September 25, 1845 – The first successful electric clock to be used in England was patented by Alexander Bain on Sept 25, 1845. The principle of this early clock is still used in electric clocks of the present time. The pendulum carried an electro-magnet which swing between two permanent magnets arranged with their N poles facing one another. The pendulum itself controlled the current which magnetised and demagnetised the electro-magnet in such a way that it was alternately attracted and repelled by the permanent magnets.

September 26, 1721—One of the earliest English patents for a pump was granted to John Orlebar on Sept 26, 1721. The inventor claimed "an entire new method of raising water by a much deeper, extensive and more expeditious way of sucking and foreing it than was ever yet or could be effected by the leaver and crank" The method, however, does not appear to have been sufficiently expeditious to have been much used.

September 27, 1825.—The commencement of the railway era may be said to date from the opening of the Stockton and Darlington Railway, which was the first public railway in the world on which steam locomotives were used. George Stevenson was the engineer. The line, with branches, was 36 miles long. It was a single track with passing places every quarter mile. The capital expenditure on the line was nearly £170,000. It was opened on Sept. 27, 1825.

September 28, 1852.—Henri Moissan, born on this date, was one of France's most illustrious scientists. A long series of researches on compounds of fluorine, began in 1884, led to the isolation, for the first time, of fluorine itself. Investigation of gaseous fluorides of carbon with the view of liberating the carbon in the form of diamond by removal of fluorine from the compounds failed. This failure led to the successful attempts to make artificial diamonds by the sudden cooling of molten iron containing carbon in solution. In order to obtain the necessary high temperatures, Moissan devised the electric furnace.

September 29, 1892.—On this date Lord Rayleigh addressed a letter to NATURE directing attention to his discovery that introgen prepared from air had a density greater by I part in 1000 than that prepared from ammonia Investigation by Rayleigh and Ramsay of the cause of the disagreement led to the discovery and isolation of the mert gas, argon. This was followed soon after by Ramsay's isolation of helium from the mineral elèveite

September 30, 1880.—The first astronomical photographs were made in 1840 by J. W. Draper, using daguerreotype plates. Draper's last great photographic achievement was a record of the great nebula in Orion, made on Sept 30, 1880. Attempts at improving on this first effort were cut short by Draper's death. On Jan. 30, 1883, however, Dr. A. Ainslie Common secured a picture far superior to any which had previously been taken.

October 1, 1840—William Henry Fox Talbot is best known as one of the founders of photography. He discovered 'photogenic drawing,' produced by the action of light through leaves, etc., in contact with silver chloride paper, fixation of the photographic image by potassium iodide or by washing in salt water, and evolved the method of printing positive images from transparent negatives on paper. He applied his genius in other spheres, and on Oct. 1, 1840, was granted a patent for an engine "for obtaining motive power" by electrical means. W. C.

Malquori · The system Fe(NO<sub>3</sub>)<sub>3</sub>: Al(NO<sub>3</sub>)<sub>3</sub> H<sub>2</sub>O at 25° Feric and aluminium intrates form neither additive compounds nor mixed crystals at 25°. The solid phases in equilibrium with the saturated solutions are  $Al(NO_3)_3$ ,  $9H_2O$  and  $Fe(NO_3)_3$ ,  $9H_2O$  respectively for the two branches of the solubility isotherm -G Natta and E. Casazza · Crystalline and atomic structure of ferrous hydroxide · The results of examination by the powder method and of the study of the photometric intensity show that ferrous hydroxide crystallises in the holohedral class of the rhombohedral system with a structure analogous to that of brucite The elementary cell, containing one molecule, has the dimensions a = 3 24, c = 4 47, c, a = 1 38 The calculated density is 3.40 and the structure appears to be ionic—M Comel Action of  $p{\rm H}$  on muscular pulp in the presence of phosphate ions

#### SYDNEY.

Royal Society of New South Wales, Aug 3-Sir George Knibbs. Rigorous analysis of the phenomena of multiple births. The number of cases of maternity and of the resulting numbers of twins, triplets, and quadruplets, are given for each year from 1890 to The frequency of twms changes very slowly with time, but increases linearly with age up to age 37 years, and then decreases linearly with age from 37 to 49 years. The probability of giving birth to twins through the division of an ovum after fertilisation, is sensibly a constant quantity throughout the productive period of female life; that is, it bears a constant ratio to the number of cases of maternity. The relative frequency of the production of twins from two ova, however, varies systematically with the age of the mother. The number of cases of triplets was not sufficiently large to admit of an exhaustive analysis, but the distribution shows that it is a function of the mother's age, the maximum frequency being at about age 35 years—W. L Waterhouse: Studies in the inheritance of resistance to leaf rust, *Puccinia anomala* Rostr, in crosses of barley (1) More than a hundred varieties of barley obtained from various countries and belonging to six species were tested to determine their reaction to an Australian physiological form of Puccinia anomala The majority of the varieties were quite susceptible, but all the resistant varieties had some characters which were agronomically undesirable. Cross-breeding work involving these resistant sorts and the commercially valuable susceptible types was undertaken. The  $F_1$  plants showed complete dominance of resistance. In the  $F_2$  there was segregation in the ratio of 3 resistant plants to 1 susceptible. The F<sub>3</sub> results confirm the hypothesis that a single dominant genetic factor underlies resistance. Evidence of linkage between rust resistance and morphological characters was lacking in the cases examined. There is an indication of correlation between resistance to Helminthosponium sativum and Puccinia anomala in certain of the varieties—M. B. Welch: The wood structure of some species of Kauri. Macroscopical and microscopical details, together with the principal uses and physical properties, are given six species of Kauri which find their way as ole mercial timbers to the Sydney market The hese tion in individual species renders identifies

1,

difficult. The plugs of phlobaphene material in the tracheids are described and the occurrence of wood parenchyma, usually regarded as being absent in the normal secondary wood of the Araucarmeæ, is noted.

# The World Population Conference.

THE head of a social research department, such as exist on the other side of the Atlantic, who was on the outlook for a subject for a student's thesis, might do worse than suggest the modern phenomenon of conference holding as suitable for investigation Attendance at conferences and congresses threatens to consume an increasing proportion of the lifetime of scientific workers If the laborious method of investigation which finds favour in certain places was followed in the department, we may suppose that the student would classify the motives for organising conferences and the methods of procedure followed, and would finally attempt to correlate different procedures with the 'results' attained. Such a student might find it difficult to fit the recent World Population Conference at Geneva into any well-defined category. On one hand, the programme was limited to the strictly scientific discussion of certain aspects of the population problem On the other hand, it is probably correct to say that in the minds of most of those who attended was the conviction that the regulation of the quantity, quality, and distribution of population is a world problem which the organised communities of the world have to face at no distant It was a conference of biologists, statisticians, and economists, who did not trespass into the province of the politicians, but for the most part realised keenly the need for an agreed international policy if ordered progress is to be secured

The problem of migration was discussed at the conference, and it is in connexion with the difficulties arising from migration that the politician is first called upon to deal with practical population problems. It is only within the last few years, owing to the admirable work of the International Labour Office, that trustworthy and comprehensive statistics of migration have become available. These deserve careful analysis and discussion, which should be of practical use. But it may prove to be true that, once the forces leading to a desire for migration have been generated, it is beyond the skill of statesmen, however well informed and well intentioned they may be, to arrange a peaceful solution of the problem. It is necessary, therefore, to inquire into the nature of these forces in the hope that civilised nations may attempt to control them. Since migration is a most complex phenomenon, we are led to study the more fundamental aspects of the whole question, all of which bear upon migration. These

are such as the biological problems of fertility, the economic problems of optimum density, and the social problems of family limitation. The hope is that civilised nations will learn in time to found their internal policies upon such knowledge as may be accumulated upon these matters. In this way maladjustments may be avoided before their results coalesce and manifest themselves in the form of pressure to migrate. This they will only do if they realise that in the end national well-being coincides with international well-being

This programme sounds sufficiently chimerical, even though we have limited it to civilised States There can be little doubt, however, that a common action by civilised States is urgent. United upon a population policy, they may be able to maintain world order in face of developments in Asia which We now know, thanks to the seem inevitable recently published researches of economic historians, the true story of the great outpouring of population m the western world during the last century. It was due not to an increase in the birth-rate, but to a decrease in the death-rate In all likelihood events in the East will follow the same course Indeed, in India events are now taking this turn Since we cannot anticipate that any effective efforts will be made to guide events in the East so as to avoid the otherwise mevitable pressure towards migration, the only hope lies in a western world united in a common policy based upon a common basis of scientific investigation, and thus strong enough to control the situation If, on the other hand, the so-called civilised States embark upon competitions in numbers, they may well come to grief, quite apart from the fact that the eastern races will inevitably beat them at the game

It is a commonplace remark that the value of scientific conferences hes in the opportunities of personal contact, and not in the formal communications or discussions. It is only the readers of the popular press who imagine that great discoveries are announced at congresses. This is not quite as true of the social sciences as of the natural sciences. The mechanism for distributing the results of research work in the natural sciences seems to be in advance of that in the field of the social sciences. It was interesting to observe that when biological matters were under discussion, the results of recent research were more generally familiar than when social phenomena took the first place on the programme. Apart from the value of contact and of disseminating information on certain matters, the conference has achieved a distinct success in that it has decided to set up

the nucleus of a permanent organisation for the study of population problems. It cannot yet be said what form this will take. But if out of it grows an organisation of a truly international character, with the prestige of the full support of the representatives of the relevant sciences behind it, the conference will stand out as a notable event. The habit of international consultation on the scientific aspect will grow, and this cannot fail in time to influence international policy.

The function of a permanent international organisation might thus be twofold. The greater the prestige it gams, the more unlikely will it be that international policy will be directed regardless of the findings of biologists and economists would not be a propaganda organisation except in the sense that it would assist to disseminate facts. Again, a most useful piece of work lies in the correlation of investigations in different fields. The practical problems of population are complex problems. The biologist, the statistician, and the economist all have, for example, something to contribute towards the solution of the problem of migration A deliberate effort is, however, required in order to give due weight to the various contributions in such a fashion that practical policies have regard to all the more important factors involved It was evident enough at the conference that workers in different fields who have become interested in practical problems look at these problems only too often from a very narrow angle An international organisation might do good work in opening the eyes of specialists to the necessity of taking the results of workers in other fields into account before they deliver their opinions as experts upon problems which they have not fully envisaged

So far as it affects Great Britain, one aspect of the present situation, which is not without its importance, deserves a word of comment. It is not to be supposed that population problems when discussed at conferences or elsewhere will be referred to in the popular press unless they can be dressed up to justify a good headline or to form a sensational paragraph But it is disappointing to notice that the more responsible organs in Great Britain appear to be committed more of less to a boycott of these matters. The reference is not to this conference in particular so much a to events here during the last few years. We havt still a long way to travel towards a rational policil when editors of responsible papers regard popula tion problems as too indelicate or too dangerou. for discussion in their pages. A. M. C-S. s

# The Homologues of Carbon.

A Comprehensive Treatise on Inorganic and Theoretical Chemistry By Dr J W Mellor Vol.
7 Ti, Zr, Hf, Th, Ge, Sn, Pb, Inert Gases Pp x+977. (London. Longmans, Green and Co, Ltd, 1927) 63s net.

THE writer of a 'comprehensive treatise' is in grave danger of being drowned by the torrent of information which flows in upon him as soon as he accepts the responsibility of taking cognisance of all the details of his chosen subject. It is almost a commonplace that the amount of readable matter in such a treatise (like the pressure of a gas) is inversely proportional to its volume On this basis of calculation, it might be expected that a treatise on chemistry which has only reached Group IV of the Periodic Classification in a seventh volume of 1000 pages would be intolerable in its dullness. It is therefore a welcome relief to find that the opening sentence of Dr. Mellor's new volume has the arresting character which one might expect to find at the beginning of a detective story "In 1791, W Gregor studied the black sands of Menacan, near Falmouth, Cornwall, and found some greyish-black granules which were attracted by a magnet" The sleuth then sets to work to solve his riddle with the help of hydrochloric and sulphuric acids, ammonia and potash-lye, and finally brings in tincture of galls as a means of checking a possible alibi, and ends by confiding —to Crell's Chemical Journal instead of to his friend Watson-his conclusion in the following terms:

"The extraordinary properties of the sand have led me to believe that it contains a new metallic substance. In order to distinguish this substance from others, I have ventured to suggest a name derived from the neighbourhood—Menacan, Cornwall—where it was found, and therefore I propose to call the metal menacanite."

If the narrative lacks the element of horror, which is such an asset to the writer of detective stories, it has at least the merit of taking us to the romantic west, to speculate whether the hero of the story saw the fig-tree growing out of the side of the shurch tower when he visited Menacan at the time of the French Revolution, whether he had a magnet is his pocket whilst he was reading in the church he message of Charles I. to his loyal Cornish subjects, and, finally, in what precise locality he discovered the magnetic granules. After reading in he succeeding sentences how the new element was obbed of its Cornish name and called 'titanium,' ne is impelled to breathe a lament, such as Urbain

must have uttered when 'celtium' was re-baptized as 'hafnium'

Since the volume deals with all the elements of Group IV, except carbon and silicon, the reader will turn with interest to Chap xliii. to see what the author has to say about the celtium-hafnium controversy, on which readers of Nature should be already well-informed (see vol 111, pp. 79, 182, 252, and 462) The verdict of our modern Berzelius is unequivocal—

"In 1911, G Urbain announced the discovery of a new element in some residues remaining after the separation of the lutecum-ytterbium fractions of the rare earths He called it celtium. Subsequent observations showed that all the evidence in favour of this element was worthless In May, 1922, A. Dauvillier found that the X-ray spectrum of these residues was in agreement with the presence of an element, atomic number 72, and G. Urbain applied the old term to the new element. The neo-celtium was not obtained in sufficient quantity, or sufficiently purified, to enable any other unequivocal statement to be made of its properties. Meanwhile, January 1923, D. Coster and G. von Hevesy reported a new element . . . The new element was called hafnium, Hf-from Hafnia, an ancient name for Copenhagen "

After reading these remarks it is not surprising to find that the chapter is labelled 'hafnium' and not 'celtium.'

The remaining elements of the first sub-group are zirconium and thorium, the latter being of interest both on account of its radioactivity and of its technical use in the 'incandescent gas-mantle.' These two topics form the subject of two sections in which the relevant researches are adequately reviewed.

Passing on to the other sub-group, we find a section on "The Physical Properties of Tm" which is effectively illustrated by photographs of slipbands in strained tin and of the surface of a sample of tin affected by the 'tin-pest.'

Under the heading "Physiological Action of Lead" an amazing story is told of a custom, which appears to have prevailed for many centuries, of "rendering harsh wine milder" by boiling it in lead vessels, or by the action of litharge. The htharge or white-lead was singularly efficacious in renovating spoilt wine, but its physiological effect was disastrous, producing, "according to the constitution of the consumer, a speedy or a lingering death, violent colors, obstructions, and other maladies." It was, however, so successful, from the point of view of the vendor, that its use could barely be stopped by the severest of punishments, torture and death. After this, it is difficult to

admit that the use of preservatives in tood is a purely modern vice, since it no longer seems necessary to suggest the infliction of penalties such as these merely in order to prevent the addition of boric acid (not exceeding 0.4 per cent.) to cream, or of benzoic acid to that form of coffee which is sold in a bottle instead of a tin

The final chapter of the volume deals with the "Inert Gases" This chapter relapses, perhaps inevitably, into the form of a catalogue of numerical data, alternating with long lists of authorities on a subject which has interested many workers both in physics and in chemistry. The reviewer has, however, formed the opinion that Dr. Mellor writes with more freedom and in a more interesting style as he 'warms up' to his colossal task; and the numerous illustrations, although generally reproduced on a very small scale, are of great value in setting out the precise conditions of equilibrium in scores of different systems. The photographs, which are not reduced so drastically, provide another welcome relief to the solidity of the text; and tiny diagrams, representing the results of Xray analysis of substances such as stannic iodide and the chlorostannates, show how closely the author has kept up with modern developments. He may therefore be congratulated without reserve on having arrived at his half-way house without showing any signs of weariness or flagging, since he appears to be even more fresh and vigorous now than when he first started out on his long journey. T. M. LOWRY.

# Zonæ Torridæ Tutamen.1

The Life and Work of Sir Patrick Manson. By Dr. Philip H. Manson-Bahr and Lieut.-Col. A Alcock. Pp. ix + 273 + 12 plates. (London, Toronto, Melbourne and Sydney: Cassell and Co., Ltd., 1927.) 16s. net.

In the ordinary progress of knowledge, men come and men go, each contributing according to the talents given to him, but from time to time there appears an individual whose work signals the beginning of a new era. Such a man does not merely add his own quota to the growing stream of knowledge, but seems, by some hidden power, to unlock the waters of the well of truth so that the stream becomes a flood. Such a man was Lister, whose centenary is celebrated this year, and such, too, was Manson, who stands in the same relation to modern tropical medicine as Lister does to modern surgery. It can but add to Lister's

<sup>1</sup> The motto of the Royal Society of Tropical Medicine and Hygiene, of which Manson was first president.

No. 3022, Vol. 1201

fame that the recently published "Life and Work of Sir Patrick Manson" makes known the part that Lister played in support of Manson and Ross in their pioneer work

Manson's contributions to scientific knowledge are as well known as they were varied A list of his published papers occupies twelve pages. He has been called 'Mosquito Manson.' It is true that his demonstration of the rôle of mosquitoes in relation to parasitic disease in man is the brightest single gem in his crown of achievement, but attention has been focussed too much on this one discovery. Much more than that underlay Blanchard's naming him "the father of the modern science of tropical medicine" It is fitting that the full measure of Manson's worth should be laid before the world by two men so intimately connected with him both in work and private life as Dr. Manson - Bahr and Col. Alcock. What impresses, in this record, is the bigness of the man. Here was no dry-as-dust scientist content with making additions to abstract knowledge. professional life he was a surgeon of skill and repute—and the two do not always go together-a physician of insight and mature judgment, an obstetrician whose ability and tact made him acceptable to a foreign and highly conservative race, a teacher who could attract and hold his pupils, a laboratory worker whose dexterity overcame the difficulties of place and circumstance: and his work in every sphere was illuminated by an inquiring genius which set him ever speculating, probing, searching, until basic facts and processes were laid bare. In the world of affairs he was shrewd and penetrating, with organising power and driving force which made him the effective adviser of a great department of State, and to which there remain as monuments the medical school of Hong Kong and the London School of Tropical Medicine. Of his private life too little is known, and even his biographers are compelled to sketch with uncertain pen the twenty years and more of Manson's life which were spent abroad. He was good company, kindly and courteous; tolerant of another's contrary opinion so long as it was sincerely held; a great reader, passionately fond of poetry; no mean geologist; a good man with a gun, and an angler after the heart of Isaac Walton.

Born in Aberdeenshire in 1844, Manson was a first destined to be an engineer. His youthful desire to learn 'how the wheels go round' is seen when we find him, as a schoolboy, dissecting a cather than the search and the search and the search are t

some physical frailty, turned his attention from the crude mechanisms of man's construction to the most delicate machine of all, man himself It may be, too, that the accident of the cat's containing a tapeworm determined his lifelong interest in the helminth parasites of man. Graduating in medicine at Aberdeen, he soon went abroad, settling first at Amoy and later in Hong Kong Some idea of the difficulties to be overcome may be gathered from his having had to run for his life when attempting to perform an autopsy, and from the fact that the Customs Gazette was for long his only medium of publication. His independence of character is seen in his repayment to his father, with the first-fruits of his labour, of the expenses of his medical education was liked and respected by the Chinese, and himself grew fond of them, a point brought out by Dr H M. Hanschell in an admirable pen portrait quoted by the authors. In Manson's experiences on his first return to England is found the key to his determined and successful efforts to establish definite teaching on the diseases peculiar to hot climates Impressed as he had been with his own ignorance of such subjects, he set about to acquire the fullest knowledge to be obtained in London. He found nothing save what he extracted for himself by searching the library of the British Museum.

Many pages of the "Life" are taken up by an extremely interesting series of letters from Manson to Ross, written while the latter was working to establish the mosquito-malarıa theory. This part of the book makes a vivid picture—as vivid as and truer than that painted in highly-coloured language by a recent writer in the New World . Ross in India labouring under difficulties, now making a little progress, now becoming sidetracked, now disheartened, now hopeful again as some success crowned his efforts; and Manson in London anxiously awaiting every mail, writing frequently with helpful suggestions, supporting in high places by all the influence he could wield or induce others to wield, encouraging to solve the problem before other investigators should succeed, and resterating, with a constancy which Ross might be pardoned for finding tiresome, his advice to "follow the flagellum" The outcome is known to all. Failing with the other mosquitoes, Ross succeeded with the dappled anopheles and was able to go a stage further than did Manson's hypothesis, and to show how the man-mosquitoman cycle is completed by the mosquito in the act of biting.

The account of Manson's work for the Chinese in Amoy and Hong Kong should be read by the many in China and the few m Great Britain who represent at present that the British in China have played no part save that of self-interest. Britain's history teems with the names of her sons who have gone to strange lands and have there enhanced the prestige of their race, and none more nobly than did Manson Though much of his life was spent outside the Empire and much in a colony territorially insignificant, yet he may with truth be called an Empire builder. Directly through his instrumentality, more than three thousand doctors have received expert training in those special arts and sciences without the exercise of which many of the British Empire's resources could never be tapped. His fame, like the influence of his life and work, is world-wide and abiding.

J. F. C. HASLAM.

# An Impeachment of Science.

Science: Leading and Misleading. By Arthur Lynch. Pp. 376 (London: John Murray, 1927.) 7s. 6d. net.

R. LYNCH covers a wide ground in his book on science dealing successively with mathematics, physics, chemistry, biology, physiology, medicine, psychology, and ethics. The modern sciences are so highly developed and specialised that it is unusual for a single writer to be able to discuss competently the technical details of more than a few sciences. Mr. Lynch considers that this tendency to specialisation requires correction, and with a laudable courage he attempts to put his principles into practice, mastering at the same time the technicalities of each science and explaining them in language which is intelligible to all. While, however, his book contains a great deal of scientific matter, its central theme does not appear to be so much the particular discoveries or the development of science as a criticism of current views as to the basic principles and methods of science. It is this philosophical theme which gives unity to what is otherwise a series of discursive essavs.

Mr. Lynch contends that the ordinary view or assumption as to the absolute certainty of scientific knowledge is mistaken, and he professes to establish his claim by recounting the constant mistakes committed by the great men of science of the past. The soundness of such an argument may be open to question, but the historical account given of science is often lively and interesting, although

perhaps too much is made of the small mistakes and foibles of great men When Mr. Lynch comes to philosophers such as Kant, he paints a picture which is clearly too one-sided to carry much conviction. He does not set out in this book to explain at any length his own theory as to the character of scientific certainty, but he is content to indicate a view somewhat similar to that of Mach and to refer the reader to his work on psychology for a more complete exposition.

In his first essay Mr. Lynch reviews briefly the early period when the philosophers were also the leading scientific workers. Actuated by a praiseworthy desire to make the speculations of these early thinkers live, he tends to modernise overmuch their doctrines; thus he says that in Heraclitus we find the early apprehension of the principle of evolution and also the theory of ether; moreover, he scarcely does justice to the metaphysics either of Plato or of Aristotle. According to Mr. Lynch, the subject which Plato pursued with the greatest tenacity was mathematics, but the medieval schoolmen seized upon the more obscure of Plato's doctrines and "left their malign influence to obfuscate the brains of many of our most famous and authoritative thinkers of to-day"; and while Aristotle's "Ethics" is "a work of marvellous creation," Aristotle was nevertheless not strong in the "field of psychological analysis."

If Mr. Lynch takes a 'rationalist' view of medieval Platonism and is also hostile to modern absolute idealism, he is equally sceptical both of the scientific and of the philosophical theories of relativism. If his chapters on relativity have been understood aright, he thinks that Einstein has added very little to the body of scientific knowledge, and that his theory is rather a convenient formula liable to be overturned to-morrow, than a statement of an abiding truth. Philosophical relativists, such as Lord Haldane, Mr. Lynch states have taken Polonius as their model and cannot be regarded seriously. Apparently the cure for all these fallacies and the basis for a true system of science and philosophy is to be found in a new constructive psychology.

In the latter part of his book Mr. Lynch reviews modern schools of thought, and he does not conceal his contempt for most of the leading thinkers. Bradley, Bergson, Bosanquet, the Earl of Balfour, Dean Inge, Dr. Schiller, Prof. Wildon Carr, Prof. Dawes Hicks, and others, are dismissed with none too complimentary remarks, and for universities and scientific associations generally Mr. Lynch has scarcely a good word to say. He appeals

over the heads of the professors to the great public, but he should bear in mind that while the public always likes and admires outspoken criticism, witty or caustic as the case may be, it immediately turns a deaf ear if it suspects a personal grudge or ill temper

# The Increase of Epidemic Diseases of the Nervous System.

Epidemic Diseases of the Central Nervous System. By Dr. Arthur Salusbury MacNalty. Pp. xiii + 194. (London. Faber and Gwyer, Ltd. (The Scientific Press), 1927) 12s. 6d. net.

LIFE and its incidents are always changing, new fashions and phenomena come and go and fashions and phenomena come and go, and among these our diseases alter not only in name but also in nature. With the more rapid means of communication the rate of living, though not longevity, has increased, and, like most generations, the present complacently condoles with itself on the increased strain of modern life. Neurology has made enormous advances in recent years, and, as a result, many new diseases have become recognised, but apart from the influence of this addition to knowledge there appears to be an increasing susceptibility of the central nervous system to attacks of epidemic disease, such as acute poliomyehtis during this century, during the special conditions of the War cerebrospmal fever, and since the later years of the War a practically new disease, epidemic or lethargic encephalitis, known in the lay press as 'sleepy sickness,' which should be distinguished from the sleeping sickness of more tropical climates, due to infection with trypano-

The endowed lectures at medical institutions offer an opportunity for the publication of original investigations and for surveys of current knowledge. The appearance in an expanded form, with more recent additions, of the scholarly Milroy Lectures on "Epidemic Diseases of the Central Nervous System," given in 1925 before the Royal College of Physicians of London by Dr. A. Salusbury MacNalty, of the Ministry of Health, and dedicated to his former teacher, the president of the College, Sir John Rose Bradford, provides convincing proof of the value of such endowments. Dr. MacNalty had much to do with the early investigation of encephalitis lethargica, first described early in 1917 by Economo and von Wiesner in Vienna, and attracting attention a year later in England, where it was first suggested to be botulism, a very rare disease in Great Britain, of which the only definite

outbreak occurred in 1922 at Loch Maree from eating infected potted duck paste.

Well equipped in epidemiology, Dr MacNalty is therefore able to give an admirable account of the epidemic nature and history of the three diseasesacute poliomvelitis and polioencephalitis, cerebrospinal fever, and encephalitis lethargica—not only in man but also of what is known about their occurrence in animals Since the end of the War the incidence of cerebrospinal fever has greatly diminished, but unfortunately the reverse applies to the other two, both of which are due to infection with an ultra-microscopic virus spread by healthy 'carriers' The after-effects of encephalitis lethargica on the brain, which may follow acute attacks so slight as to pass almost or quite unnoticed, are calamitous; when the incidence of abortive attacks and of its form, or the closely allied condition, known as epidemic hiccup, which do not appear in the notification returns, are taken into account, the increase becomes positively alarming. A thorough knowledge of the causation and epidemiology of these diseases is most important in providing efficient means for their prevention, a subject on which Dr. MacNalty also touches, and hence this well-written and detailed account of their epidemiology is most appropriate. H. R.

### Our Bookshelf.

Lehrbuch der Geophysik. Herausgegeben von Dr. B. Gutenberg. Lieferung 3. Pp. 401-608. (Berlin: Gebrüder Borntraeger, 1926.) 12 gold marks.

The third instalment of the work edited by Prof. Gutenberg maintains the standard of the first two. It begins with a clear and up-to-date account of terrestrial magnetism by Dr J. Bartels. One learns in it that the whole energy of the earth's permanent magnetic field is equivalent to that of the radiation received from the sun in three seconds!—or, it may be remarked, to the gravitational energy released by a radial contraction of the order of  $10^{-6}$  cm. Prof. Gutenberg then devotes sixty-six pages to the physical constitution, figure, density, and thermal state of the earth. In a useful, if brief, account of the figure of the earth, the Radau approximation is given, but neither Darwin nor Callandreau is mentioned.

Present knowledge of the distribution of density is well summarized. The three physical states of matter are clearly defined on p. 455. The distinguishing mark of a gas is its high compressibility, while a solid is distinguished from a liquid by the possession of a measurable rigidity, or elasticity of form, which liquids have not. Glasses are therefore regarded as solids, and not as liquids. But Gutenberg seems to contemplate seriously the possibility that all solids have a finite viscosity; the proposi-

tion is perhaps worth consideration, though neither experiment nor theory lends it much support. The work of Bridgman, Tammann, and others on the properties of matter at high temperatures and pressures is described. Methods of measuring gravity and its variations with position are treated fully by Prof Ansel, with special reference to the detection of masses of abnormal density near the surface. An account of electric currents in the crust is then given by Bartels.

The last chapter, by Gutenberg, deals with the application of seismological methods to the investigation of the uppermost layers of the crust. Until recently seismology, so far as it has dealt with the sedimentary layer at all, has usually regarded it mainly as a nuisance But the problems it involves are now being attacked, and this chapter is, I believe, the first connected account of the results. Artificial shocks, such as explosions or even the fall of a heavy body, are recorded on instruments with magnifications of the order of amillion, so that movements of almost molecular extent can be detected. The sound wave in the air is a prominent feature of the records. The velocities of compressional waves in the sedimentary rocks are notably less than in igneous ones, of the order of 2 km /sec. as against 5.4 km to 8 km./sec. Distortional waves have hitherto been found more difficult to observe.

H. J.

Mind and its Disorders. a Textbook for Students and Practitioners of Medicine. By Dr. W. H. B. Stoddart. (Lewis's Practical Series.) Fifth edition. Pp. xx+593+12 plates. (London: H. K. Lewis and Co., Ltd., 1926.) 21s. net.

In the fifth edition of his well-known text-book, Dr. Stoddart has made several changes to conform with the latest ideas on the ever-growing subject of psychiatry. It is perhaps in general paralysis that there has been during the last few years the most prominent advance in therapeutics of mental disease. The section on the treatment of this disorder contains details of the modern treatment by induced malaria, and also refers to the use of tryparsamide. The main new feature of clinical psychiatry is the recognition of mental changes following epidemic encephalitis, and a chapter is devoted to this disease and its sequelæ. Dr. Stoddart's experience is that certification is rarely required, and then only for the confused type of post-encephalitic state, but cases certainly occur in which that step is necessitated by changes in the moral sphere.

The author continues to deal with psychopathology on dogmatic Freudian lines. The root of the manic-depressive psychosis is regarded as a repressed sado-masochism; the former intraneuronic intoxication theory is quite abandoned. Paranoia is said to have an invariable foundation of repressed homosexuality. Exophthalmic goitre is considered to be a variety of anxiety hysteria. It is left undecided whether dementia præcox is primarily organic or psychogenic. While these views may not find general acceptance, they form excellent illustrations of the psycho-analytical

method, which, however far it may be removed from his own ideas, must receive the consideration of every psychiatrist

Principles of Human Geography. By P Vidal de la Blache Edited by Emmanuel de Martonne Authorised translation from the French by Dr Millicent Todd Bingham Pp xv+511+6 plates (London Constable and Co, Ltd, 1926) 18s net

HUMAN geography is a new subject, but its facts It is the outcome of the growth of ideas rather than the result of discovery Man is not an abstraction in the world in which he lives, but his evolution is related to the environment in which The study of environment is not static but one that involves continual change in values as man evolves Prof Vidal de la Blache shows that there is more in geography than merely a study of the stage on which man has played his part, for man himself is a geographical factor changing and moulding his environment, and the study of progress entails a study of his struggles with physical and other obstacles. His distribution over the globe and his varying degrees of progress are the expression of the geographical conditions he has met.

The book is incomplete except for the early chapters on the distribution of population, and it has been put together from the author's notes after his death. Some of the more interesting sections on the factors of civilisation and the growth and influence of transport are fragmentary, but long enough to show the author's trend of thought Fortunately, some important maps were complete and are included. In spite of its imperfections, the book is an important contribution to a side of geography which is specially associated with French workers.

Körper und Keimzellen. Von Prof Jürgen W. Harms. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 9.) Teil 1. Pp. x+516. 33 gold marks. Teil 2. Pp. iii +517-1023. 33 gold marks. (Berlin Julius Springer, 1926.)

The author, holding that a proper understanding of the relation of germplasm to soma is a prerequisite in the investigation of all problems of biology, has set himself the task of giving in broad review an account of the established facts concerning this relationship as it exists in the animal kingdom (including man) The result of his endeavour is this excellent and most useful book. The objective method of presentation, the historical review followed by a fair statement of modern opinion, the judicial comparison of opposing doctrines, the avoidance of any exhibition of preference save only in those matters upon which the author is a recognised authority, make the reading of this book both pleasant and profitable.

The subject of the endocrine activity of the gonads is treated in a most thorough manner, and any one who seeks trustworthy guidance in the Stemach-Stieve controversy will find it here. Castration,

gonad implantation, substitution therapy, and rejuvenation are discussed fully, and the rôle of the nervous system in the maintenance of the sexual characters is examined by reference to the author's well-known work concerning the thumbpad of the frog. The bibliography does not include all the names and papers to which reference is made in the text.

This work, into which Harms's earlier book is worked in ("Die innere Sekretion der Keimdrusen," Jena, 1914), can be warmly recommended. Not the least of its good qualities is that the author indicates everywhere lines of profitable research.

Indicators their Use in Quantitative Analysis and in the Colorimetric Determination of Hydrogen-Ion Concentration. By Dr I. M. Kolthoff An authorised translation based upon the second German edition, revised and enlarged, by Dr. N Howell Furman Pp. xii +269. (New York: John Wiley and Sons, Inc., London Chapman and Hall, Ltd., 1926) 17s. 6d. net

Until the development of the conception of hydrogen-ion concentration, the use of indicators was confined within more or less empirical boundaries. It is therefore only during comparatively recent years that any appreciable insight has been obtained of the principles underlying the reactions of these bodies

The volume under notice fully realises the avowed intention of its author to present a treatise the practical nature of which should be developed from theoretical considerations, without being overwhelmed by them. In the early chapters dealing with neutralisations generally, with amphotoric compounds and with the colour change of indicators experimental examples are described, wherever possible, to illustrate the various points as they The uses of indicators in quantitative neutralisations and in the colorimetric determination of hydrogen-ion concentration, with practical applications, are then discussed Short chapters deal with indicator papers and with the theories of the colour changes of indicators, as distinct from the causes which bring about such changes.

Apart from an occasional loose phrase, the translation is well done; misprints are but few. Some useful tables and indexes conclude a volume which merits careful study by those who desire to obtain fullest benefit from the intelligent use of indicators.

B. A. E.

Atoms and Molecules being Part I and Chapter xii. of "The Foundations of Chemical Theory." By Prof. R. M Caven Pp. viii + 141. (London and Glasgow: Blackie and Son, Ltd., 1927) 7s net.

THE chapters which have been retained in this abbreviation deal with atomic and molecular theories, atomic and molecular weights, valency and chemical constitution, classification of the elements, the modern view of the atom and the molecule, and finally the colloidal state. The chapters omitted have reference chiefly to the states of matter, the properties of solutions and the various types of chemical change.

#### The Origin of the Nebulium Spectrum.

In the spectra of the gaseous nebulæ several very strong lines are found which have not been duplicated in any terrestrial source. Many lines of evidence point to the fact that the lines are emitted by an element of low atomic weight. Since the spectra of the light elements, as excited in terrestrial sources, are well known, this leads to the conclusion that there must be some condition, presumably low density, which exists in the nebulæ, that causes additional lines to be emitted.

A type of line, which one would expect to be affected by density in this manner, is that caused by a jump from a metastable state to a lower level. Such a metastable state is usually considered to be one from which jumps are very improbable, that is, one of which the average life is very long. Consequently, under terrestrial conditions, where the time between impacts is a very small fraction of a second, the metastable atom, in general, will be dropped down to a lower state by collisions of the second kind or by impact with the walls long before the return would take place spontaneously with the emission of radiation. Under conditions in the nebulæ, however, the time between impacts is very long, and many of these atoms will have a chance to return to lower states with the emission of radiation corresponding to the difference in energy between these metastable states.

Since the nebulæ are known to emit the well-known spectra of highly ionised nitrogen and oxygen, these ions at once suggest themselves as possible sources of the unknown lines as well.

In a four-electron system such as  $N_{\rm II}$  and  $O_{\rm III}$  the lowest energy levels are due to the configuration of 2 (2s) and 2 (2p) electrons. According to the Hund theory, this configuration gives rise to  $^3P$ ,  $^1D$ , and  $^1S$  terms. All but the lowest of these are metastable, since any jump between them involves a zero change in the azimuthal quantum number. In a five-electron system such as  $O_{\rm II}$ , the normal configuration of 2 (2s) and 3 (2p) electrons forms  $^4S$ ,  $^2D$ , and  $^2P$  terms. These are likewise metastable.

The frequency of lines due to jumps between these terms can be calculated accurately in only two cases, namely,  $^1D^{-1}S$  of  $O_{\rm III}$  and  $^2D^{-2}P$  of  $O_{\rm II}$ . The calculated frequencies, if unresolved, are 22916 and 13646,which correspond to wave-lengths of 4362 54 Å.U. and 7326 2 Å U. respectively. Two of the strongest nebulium lines are found at 4363 21 Å.U. and 7325 Å.U. These deviations are well within the rather large experimental errors arising from the fact that the values are calculated from the difference in frequency of lines in the 500 Å.U. region.

Another group of which the position can be predicted roughly is  ${}^4S^{-2}D$  of  $O_{II}$ . Both terms have been calculated from series relationships, but as no intercombinations between quartets and doublets have been found, the predicted frequency is only approximate. The predicted frequencies of the two components are 27157 and 27175, which correspond to wave-lengths of 3681·25 Å.U. and 3678 81 Å.U respectively. The strongest two nebulum lines in the ultra-violet are at 3728 91 Å.U. and 3726·16 Å.U. The doublet separation checks well and uncertainties

in the adjustment of series limits for either the quartets or the doublets can account for the deviation in wave-lengths

The strongest lines in the whole nebulium spectrum are the pair at 5006 84 Å U. and 4958.91 Å U. These have a separation of 193 frequency units, which is in almost exact agreement with the separation of 192 units observed for  $^3P_1$ - $^3P_2$  in  $O_{\rm III}$ . This at once suggests that these two lines are  $^3P_2$ - $^1D_2$  and  $^3P_1$ - $^1D_2$  respectively. The relative intensity of these two lines is just what would be expected.

Another strong pair occurs at 6583 6 Å.U. and 6548 l Å.U., showing a separation of 82 3 frequency units. This agrees very well with the known separation of 82 7 for  ${}^3P_1 {}^{-3}P_2$  in  $N_{\rm II}$ . It these lines are identified as  ${}^3P_2 {}^{-1}D_2$  and  ${}^3P_1 {}^{-1}D_2$  of  $N_{\rm II}$ . one can calculate at once the term value of  ${}^1D_2$ , since those of  ${}^3P$  are already known. This  ${}^1D$  term should combine strongly with the  ${}^1P$  term of the  ${}^3P$   ${}^3$  configuration and the  ${}^1D$  term of the  ${}^3P$   ${}^3$  configuration. The term values of these singlet terms have already been determined accurately by Fowler. The calculated positions of the lines arising from these combinations, obtained with the use of the above nebulium lines, are 746 98 Å U. and 582 15 Å U. Strong lines are observed in the nitrogen spectrum at 746 97 Å U. and 582 16 Å U. This furnishes almost certain proof of the identification of this pair of nebulium lines.

identification of this pair of nebulium lines. The other lines to be expected, on the above hypothesis, from  $N_{\rm II}$ ,  $N_{\rm III}$ ,  $O_{\rm II}$ , and  $O_{\rm III}$ , fall outside the range of wave-lengths easily observable in nebulæ. The above identifications account for all but two or three of the strong nebulium lines. It should be noted that in every case where it has been possible to make an exact prediction, a strong nebulium line has been observed at the calculated place. Furthermore, the above identifications are entirely in accord with the behaviour of these lines in the nebulæ as observed by Wright.

The nebulium lines thus far identified are collected in Table I.

	TABLE	I.
λ	Source.	Series Designation.
7325.0	$O_{II}$	$^2D$ - $^2P$
$6583\ 6$	$N_{II}$	${}^{3}P_{2}$ - ${}^{1}D$

### The Function of Water Vapour in the Photosynthesis of Hydrogen Chloride.

EVIDENCE was presented (B. Lewis and E. K. Rideal, J. Chem. Soc., 129, 583 and 596; 1926) for the view that the photo-expansion of bromine and other halogens in the presence of water vapour (Budde effect) is due to heat liberated by the recombination of halogen atoms set free by the absorption of light quanta. Although absorption of radiation occurs in the dry gas, no Budde effect is observable (J. W. Mellor, J. Chem. Soc., 81, 1280; 1902; Lewis and Rideal, loc. cit.) even when the gas is subjected to an intense source of ultra-violet radiation (E. B. Ludlam, Proc. Roy. Soc. Edinburgh, 44, 197, 1924). This is interpreted to mean that the halogen does not dissociate in the dry state; that the radiation absorbed

activates the halogen molecule for a short period of time and is then emitted (presumably as longer wave-

It has been shown by several workers that the photo-chemical union of hydrogen and chlorine does not proceed in visible radiation in the absence of water vapour. Of the numerous mechanisms proposed for this reaction, the Nernst atomic chain still remains on the whole the most plausible. The formation of hydrogen bromide from the elements is known to proceed by way of bromine atoms, the endothermicity of one of the atomic steps preventing long chains (for literature see Lewis and Rideal, J. Amer. Chem. Soc. 48, 2553, 1926) Lewis and Rideal (J. Amer. Chem. Soc, loc. cit) have shown that the absence of water vapour retards this reaction of space prevents adequate reply to Bodenstem and Jost (J. Amer Chem Soc, 49, 1416; 1927), but it should be mentioned that Table III., p 2558 of Lewis and Rideal's paper, presents a series of experiments on the formation of hydrogen bromide in as dry a system as was possible at the high temperatures without the use of phosphorus pentoxide, in which considerable retardation was observed, and in one case, nearly stopped completely. Two or three typographical errors prevail; the values for experiments 8 and 11 should read 45.8 per cent. and 56 per cent., and in the last column 52 2 per cent. belongs to experiment 10

It is generally agreed that the high quantum yield in the photo-synthesis of hydrogen chloride is due to some chain mechanism involving chloride atoms. Since the mechanism of the Budde effect is probably the primary step in this reaction (Bernard Lewis, Trans. Far. Soc., 21, 585; 1926), and if the atoms which initiate the chains are absent, then it follows that the latter cannot be initiated in the absence of water vapour. There seems to be no evidence that water vapour functions in the chain itself as was proposed by Coehn and Jung (Ber. 56, 696; 1923) and Coehn and Heymer (Die Naturwissenschaften, 14, 299; 1926) from the observation that the dry gases did not combine in the visible but did so in the ultraviolet. For the purpose of brief discussion these two

mechanisms will be reproduced here.

A. Moist hydrogen and chlorine: in visible light.

(1)  $\text{Cl}_2 + \text{h}_{\nu}$  (small) =  $\text{Cl'}_2$ (2)  $\text{Cl'}_2 + \text{Cl}_2$  =  $\text{Cl}_2 +$ (3)  $\text{Cl} + \text{H}_2 \tilde{\text{O}}$  = HCl $= \frac{\text{Cl}_2}{2} + 2 \text{ Cl}$ = HCl + OH(4) OH + H<sub>2</sub>  $= H_0O + H$ (5) H + Cl<sub>2</sub> = HCl + Cl

B. Dry hydrogen and chlorine: in ultra-violet.

 $\begin{array}{cccc} \text{(1) Cl}_2 + \text{h}_{\text{I}} \text{ (large)} &= \text{Cl}''_2 \\ \text{(2) Cl}''_2 + \text{Cl}_2 &= \text{Cl}_2 + 2 \text{ Cl} \\ \text{(3) Cl}''_2 + \text{H}_2 &= \text{Cl}_2 + 2 \text{ H} \\ \text{twice (4) H} + \text{Cl}_2 &= \text{HCl} + \text{Cl} \\ \text{(5) Cl} + \text{Cl} &= \text{Cl}_2 \end{array}$ 

Reaction (2) in both mechanisms is unnecessary, since we know that non-polar (Franck, Trans. Far. Soc., 21, 536; 1926) and polar (Kondratjew, Z. f. Physik, 39, 191; 1926; Bernard Lewis, NATURE, 119, 493; 1927) molecules undergo optical dissociation in a single act without collision. It has been pointed out that the time between absorption and dissociation for these simple molecules must be shorter than 10-10 sec. (Bernard Lewis, Proc. Nat. Acad. Sci., in press). If atoms can be formed in the dry gas, then since (1) and (2) in B are confined to one step without collision, the dissociation of the halogen would have occurred before (3) could take place. lower hydrogen pressures the quantum yield would be less than one. If we agree that (2) does take place in the dry gas, then in a 1:1 mixture of hydrogen and

chlorine (2) may occur more often than (3), due to the smaller heat of dissociation, and the quantum yield would again be less than one Altering the relative concentrations would also affect the yield It is difficult to see why chlorine atoms resulting from (2) and (4) in B cannot propagate chains as in

### $Cl + H_2 = HCl + H$ ,

for this reaction still remains thermodynamically possible from latest thermochemical data In this case chains, and therefore high quantum yields, would be expected Mechanism B, for the dry gases, cannot explain satisfactorily the theoretically predicted quantum yield of two which was in general realised by Coehn and Heymer

The chain mechanism in A for the moist gases is extremely doubtful Considerable doubt has been cast on (3) by Norrish (Trans. Far Soc, 21, 575, 1926). Thon (Fortschritt d chem Phys, 18, 60-67, 1926), after certain considerations, concludes with Lewis and Rideal (J. Am Chem Soc, loc cit.) that the action of water is physical and therefore does not

enter into the chain mechanism

It can be shown approximately that reaction (4) in A is endothermic to such an extent that the small efficiency of fruitful collisions between OH and H2 would cut the chains very short. Thus an essential step in the chain is not always effective, if indeed it is at all, and the mechanism therefore is inadmissible.

Until evidence to the contrary is available, the mechanism of the moist reaction must be considered as a primary dissociation of the halogen under the influence of water vapour followed by an atomic chain, either that of Nernst or one suggested by Thon (Z. phys. Chem., 124, 327; 1926). The dry reaction is most simply explained by activation of a chlorine molecule and its interaction with hydrogen molecules to form two molecules of hydrogen chloride. However, Thon (loc. cit., p. 69) suggests that a trace of oxygen in Coehn and Heymer's experiments would bring about the photo-synthesis of water in ultra-violet light and the main reaction could proceed. This could be tested by exposing a dry mixture to visible light after the reaction had just commenced by exposure to ultra-violet If this reasoning is correct. the mixture should now react in the visible.

There is a possible method of testing directly whether water vapour functions in the chain mechanism. Porter, Bardwell, and Lind (J. Am.)Chem. Soc., 48, 2603, 1926), m some important experiments on the synthesis of hydrogen chloride, have shown that the chains are of the same length whether the reaction is carried out photochemically or by means of alpha radiation Since the variation of sensitivity of the mixture produces the same change in rate of both reactions, they conclude that "this must mean that the reaction chains in both cases are of equal length, and hence the mechanisms of the secondary reactions are identical whatever they may Ionisation by alpha radiation always takes place, and thus the initiators of the chains are present regardless of water vapour. If water plays a rôle in the chain mechanism, no chains should be propagated when a dry mixture of hydrogen and chlorine is exposed to alpha radiation. On the other hand, if chains, and therefore high quantum yields, persist in the absence of water vapour, this would indicate that the latter does not function in the reaction chains. It is intended to carry out these experiments.

#### Transmutation of Elements.

SINCE the publication of my letter on the transmutation of lead in Nature of May I, 1926, I have continued the experiments in collaboration with Dr. A. Karssen and W. A. Frederikse. In the letter mentioned above I stated that our repeated experiments showed that the phenomena observed with the quartz-lead lamp and pointing to a transmutation of lead into mercury, were very difficult to reproduce. The lamp with which we obtained the photograms published was the tenth made after changing the construction from time to time to secure the most distinct results. In the hope of arriving at a still better method, and intending to distil off the mercury continually during the sparking process, the construction of the lamp was again changed. The result, however, was that, even without distillation, the lead spectrum now remained absolutely free from mercury lines.

After this very unexpected result, a lamp was constructed as nearly identical as possible with the lamp before the last modification was made. The behaviour of this new lamp was not quite the same as that of the old one; the discharges were different, the last contact was not made by a very thin jet of lead, and by oscillation all the gas was pumped out of the sparking space, which did not take place with the old lamp. Notwithstanding this, the appearance of mer-cury lines was again observed, but not so strong, and after much longer periods than before. From this we obtained the impression that the kind of discharge, being influenced by the construction of the lamp, was important here. To find another easily reproducible method, we tried now another construction which allowed sparking at high voltages, 160,000 volts and 10 milliamperes in a nitrogen atmosphere at different pressures between two solid lead electrodes, but the lead spectrum remained absolutely free from mercury lines.

Experiments of the same kind were carried out with a lamp in which the lead electrodes were heated above the melting point, but the results of all these experiments with long sparks and consequently with discharges of relatively small potential fall, gave only

negative results

In the meantime, as mentioned in another paper, we applied a different sparking method, using carbon disulphide as liquid dielectric. From the extra pure lead supplied by Kahlbaum, and treated by us in the way already described to remove every trace of mercury, two electrodes, 15 mm. thick and 2 cm. long, were made. These were mounted in two holders of steel, connected to two rods of steel, and all the steel parts were heated beforehand for twenty-four hours in an electric furnace at about 800° in an atmosphere of pure nitrogen. The steel-holders and rods treated in this way, and also the lead electrodes, were examined by the slightly altered method of Stock (Z. f. anorg. Chem., 39, 465 and 791; 1926) and appeared to be completely free from mercury.

and appeared to be completely free from mercury.

Since it was possible that, for purification, the carbon disulphide had been shaken with mercury, sulphur was added and the solution was boiled for two hours in a flask with a reflux-condenser. The solution was then distilled, and 200 c.c. of the distillate was examined. No trace of mercury was found, whilst a quantity of 0.001 mgm. mercury would have been detected easily. Now we started our definite sparking experiments at 160,000 volts and 10-20 milliamperes. Since we wished to work at this voltage, and the dispersed lead soon diminishes, the electrical resistance of the dielectric, causing a decrease of the tension, every time, as the voltage

began to decrease, the experiment was stopped until the dispersed lead had precipitated. After having sparked in this way discontinuously for one or two hours, the dispersed lead was gathered and examined. In 30 gm. of the mixture of dispersed lead and carbon, 0·1·0·2 mgm. mercury was found. The same result was obtained six separate times. Then our transformer went wrong, and it was some time before we could continue our experiments.

In the meantime I resolved to carry out an experiment, the results of which would be very convincing. It would be very important if it could be proved in repeating the experiment, after replacing only the lead electrodes by electrodes of another pure metal, of which no transmutation into mercury could be suspected, that the dispersed metal in this case is always free from mercury. I chose platinum; two platinum rods, 3 mm. thick and 4 cm. long, were mounted in the same steel-holders and the sparking experiments were repeated. The result was that the conglomerate of dispersed platinum and carbon was

found to be free from mercury.

On repeating this experiment, the result was the same; and the conclusion consequently was, that the mercury found in our sparking experiment with lead electrodes must have been formed from lead. I intended to send now a preparation of our mercury to Dr. Aston, whom I had asked to examine it in his mass spectrograph, but I preferred not to do so before we had repeated the platinum experiments several times. The third sparking experiment with platinum electrodes and with a new quantity of purified carbon disulphide gave, however, not a negative but a positive result, but not so strong as we found in our

experiments with lead electrodes.

Taking for the fourth experiment the carbon disulphide previously used in our third experiment, the result was again negative. From this it follows that the new quantity of carbon disulphide must have contained a trace of a mercury compound, probably a volatile organic one, which was not removed by the purification method applied, and it had escaped detection. Since the positive result, after sparking with platinum electrodes, had disappeared, it seemed that this mercury compound could be dissociated and removed by strong electrical discharges, and therefore we resolved to purify the carbon disulphide in future by the sparking method with platinum electrodes. The result of this method was excellent. After having sparked 750 c.c. of carbon disulphide for 1½ hours, the conglomerate of dispersed platinum and carbon was separated from the liquid, and the liquid was distilled. The distillate proved to be free from mercury. This was found not only by direct chemical analytical examination, but also by submitting the carbon disulphide to a repeated sparking process between platinum electrodes, and by examination of the conglomerate of platinum and carbon formed—about 7 grams. The conglomerate was now completely free from mercury. This carbon disulphide purified by electrical discharges was used in our next experiments with lead electrodes, I cm. thick and 3 cm. long. These experiments, repeated several times, have so far given only negative results. At the moment I am, therefore, inclined to conclude that the mercury found in our earlier sparking experiments came, certainly partly and perhaps entirely, from the carbon disulphide. This seems possible, since in these experiments a used quantity of carbon disulphide was supplemented by a new quantity of carbon disulphide purified in the ordinary way. But there is still this difficulty, that after sparking between the lead electrodes in carbon disulphide, purified in the usual way, the reaction was stronger positive than

after sparking in this dielectric between platinum electrodes, in the same circumstances as regards voltage, current strength, and time. Consequently, there is still an uncertainty, which probably will be

solved by our continued investigations.

Though the experiments, which have been mentioned here very shortly, have taken a full year, they are only the beginning of detailed investigations in different directions. Still, I feel obliged to make this communication, since I know that other investigators are repeating our sparking experiments with carbon A. SMITS. disulphide.

#### Thyroid Gland and Plumage in Chickens.

In a series of experiments now being carried out with Brown Leghorn chicks concerning the relation of thyroid gland to plumage characterisation, some interesting results are already apparent in the thyroidectomised females The operation was carried out when the birds were 6 weeks old, and 3 weeks after

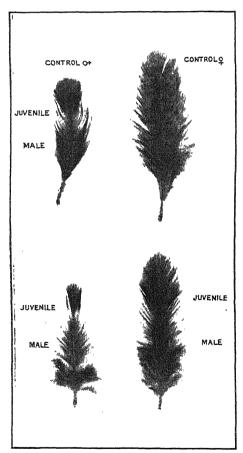

Fig. 1.—Wing contour feathers from Brown Leghorn chicks 10 weeks old. Upper figures, controls, lower figures, thyroidectomised female operated on at 6 weeks old.

the operation the effect on the plumage became visible. Changes in coloration first appear in the contour feathers of the wing, shoulder and cape, the whole forming a continuous arc of brightly coloured feathers from one wing edge to the other when the bird is examined with the wings outstretched. Examination of control male chicks at the same time showed a similar continuous band of brightly coloured feathers replacing the juvenile plumage in these areas, while no such band was present in the control females. In the region of the saddle, brightly coloured feathers were also observed in the thyroidectomised females and in control males, while being absent in control females.

When the feathers were sufficiently grown to determine their shape, it was seen that the majority of these brightly coloured feathers have the blunt tip characteristic of the juvenile feather. At a short distance from the tip, however, the shape changes abruptly, and in the proximal portion the feather is very similar to the typical male feather from the same regions, i.e. it is heavily fringed and tapers almost to a point at the junction with the distal juvenile portion This condition is also found in feathers from control males of approximately the same age (Fig. 1). The coloration of the male-like feathers in the thyroidectomised females, while markedly differing from female colouring, is not quite so deep as that of the feathers from control males.

It would appear thus that the removal of the thyroid gland from Brown Leghorn female chicks leads in the first place to the assumption of plumage of a type approaching in colour and form that of the male. These results are of special interest in view of the recent work on the effect of thyroid feeding on A. W. GREENWOOD. J. S. S. BLYTH. the plumage of the fowl.

#### Ultrasonic Stationary Waves.

THE observations described in the striking experiment of Hubbard and Loomis (NATURE, Aug. 6, 1927, p. 189) are another example of the important conclusions which may be derived from a study of the interesting phenomenon of ultrasonic stationary waves. Velocities of sound in various liquids were determined here by the ultrasonic stationary wave method some years ago; some of these results have already been published (*Trans Roy Soc. Can.*, 3, 141; 1923, 159, 191, 197; 1925; 79; 1927); others were reported to the Canadian Research Council (Report, Boyle and Morgan, 1924). The 'detector' of the standing waves in these experiments was 'nodal dust figures,' something like the figures in a Kundt's tube, but less precision was claimed for the results than is claimed by the authors above.

Pierce also carried out very precise experiments on the velocity of sound in gases (*Proc. Amer. Acad.*, 60, 6, 271; 1925) by the ultrasonic method, the detector of the standing waves in his experiments being a milli- or micro-ammeter in the associated grid-circuit of the electric generating tube. In fact, Hubbard and Loomis's experiment does for liquids what Pierce's did for gases, with the exception that their standing wave indicator is a neon tube instead of a milli-

ammeter.

The purpose of this note is to point out that the presence of these ultrasonic stationary waves in a liquid can easily be demonstrated and visualised by making use of another phenomenon, namely, that of ultrasonic cavitation, or the production of bubbles in the liquid by the waves themselves. In our work in this laboratory nodal layers of bubbles, a half wavelength apart, have been produced in a tank of liquid between an ultrasonic generator and a reflector; and some months ago Messrs. Taylor and Sproule arranged an apparatus for ultrasonic waves in which a hell-jar

was sealed to the face of an ultrasonic generator Liquid was poured in the bell-jar and the pressure in the air-space above it could be reduced by a connected pump. On working the generator, stationary waves were produced in the vertical column of liquid above it, the air-liquid surface serving as reflector pressure in the bell ar and the voltage applied to the generator could be adjusted to result in the production of either large or small bubbles in the liquid. When large bubbles were produced they rose rapidly through the liquid, but the small bubbles, especially at very high frequencies, could be made to stay suspended in the liquid in layers parallel to the reflecting The layers were half a wave-length apart, and measurements of wave-lengths and velocities could readily be effected. Our purpose, however, was not to measure wave-lengths but to study cavitation, on which subject papers are in course of publication.

The experiment is a very striking one, and in our work the nodal layers of bubbles were particularly regular and distinct at frequencies around 170,000 cycles per second. In addition, and as pointed out by Hubbard and Loomis, the column of liquid can be thrown into resonance, the condition of exact resonance in our experiment being indicated by a slight humping of the liquid at the free surface. The height of the hump depends on the intensity of the radiation, and if the liquid be slowly drained from the bell-jar the humping recurs every time the free surface passes through the nodal levels. In this way incidental measurements were taken of half-wave lengths and velocities

In all the determinations of velocity of sound by the ultrasonic method made in this laboratory in the last few years, we have found no detectable change of velocity with frequency. In solids or in liquids, within a range of frequency extending from 30.000 to 600,000 cycles per second.

# The Intrinsic Field of a Magnet.

Reasons have been given recently by J. Dorfman (Nature, Mar. 5, 1927, p. 353) and by W. Peddie (Nature, July 16, 1927, p. 80) against the view that there is in a magnet an intrinsic magnetic field of immense magnitude. It is true that an enormous intrinsic magnetic field explains simply, by analogy with the behaviour of fluids, how ferro-magnetic properties come into existence when a ferro-magnetic substance passes through the critical point from a high to a low temperature. By equating magnetic and thermal energies a formula can be obtained for the magnitude of this intrinsic field which at its maximum is, according to Weiss,  $3R\theta/\sigma_o$ ,  $\sigma_o$  being the maximum specific magnetisation,  $\theta$  the critical temperature and R the gas constant referred to two degrees of freedom of kinetic energy.

The calculation is made on the supposition that it is allowable to treat magnetic energy as the simple equivalent of the thermal energy and this leads to a value for the intrinsic field at its maximum of the order of 107 gausses, a magnitude so large that serious difficulties arise both in accounting for its origin and also in dealing with some of the facts of induced magnetism where, indeed, a small intrinsic magnetic field would be more appropriate. Undoubtedly forces of great magnitude exist within a magnet, but there are experimental grounds for concluding they are not such as give rise directly to ferro-magnetism. It seems necessary then to suppose that there are two fields within a magnet of different origin and magnitude,

one arising from magnetic forces—a true intrinsic magnetic field—and the other, and much the larger one, arising from toices which may provisionally be classed as molecular, and that there is some mechanism whereby one field can act upon the other. It is conceivable that this action is due to the magnetic ties existing between the magnetic molecules of a ferromagnetic substance, the effect of which is that translational movements of the molecules, controlled by the molecular forces and set up by the thermal agencies, give rise to rotational motion of the molecules, such motion being controlled only by magnetic forces. In this connexion Ewing's latest model of the ferromagnetic atom is helpful in showing that there may be a fixed and a movable part in the atom.

At a high temperature, when translational and consequently rotational movements are violent, orientation by an external magnetic field is so vigorously opposed that only paramagnetic qualities are in evidence. When, however, the metal cools, and elastic properties appear, the molecular forces which come into action restrict translatory motion, and consequently rotational motion subsides; as there is nothing to oppose orientation of the molecules except a small intrinsic magnetic field, ferro-magnetic properties come into existence. Thus it may be the molecular field of force and not an immense magnetic intrinsic field which brings into evidence ferro-magnetism.

This view explains how any rotational movement of the molecules, if set up by thermal agencies, must involve the energy of agitation of the whole mass, which will be very large, but if set up by magnetic agencies the expenditure of energy will be very small, which is what is observed experimentally. It is also consistent with the facts of the discontinuity of the specific heat at the critical temperature and of recalescence

Thus it is possible to reconcile the hypothesis of a very large intrinsic field which may have magnetic effects with the hypothesis that the field itself is not a magnetic field immediately controlling ferro-magnetism.

### Photoelectric Emissivity and Sparking Potentials.

In a recent paper in the Proc.~Roy.~Soc. (A, 144, 73; 1927) I have described a photoelectric theory of the sparking potentials of discharge tubes. According to this theory the sparking potential  $v_c$  is a function of the photoelectric emissivity  $\gamma$ , of the cathode, for the radiation accompanying the neutralisation of the positive ions at the cathodic surface.

It has been found possible to complete experiments upon the concomitant measurement of  $v_c$  and  $\gamma$ , for the case of a parallel disc electrode tube, with helium

as the filling gas.

A measure of proportionality of  $\gamma$ , P, was obtained by radiating the cathode with radiation proceeding from a hot wire discharge box of special form, and measuring the photoelectric effect;  $v_e$  was measured in the usual way.

The variation of  $v_c$  with progressive purification of the helium by charcoal cooled in liquid air, was unexpected and remarkable. There occurred initially the well-known rapid decrease of the values of the sparking potential until a minimum value was attained. After this, a slow rise in sparking potential took place, until a value of anything from about 10 volts to 600 volts (according to gas pressure, etc.) higher than the minimum was attained.

Introduction of additional helium showed that the effects did not proceed from pressure changes.

Concomitant measurements of P showed a fall

from a maximum at the minimum sparking potential to a minimum at the final sparking potential

After considering a number of explanations of the

phenomena, the following was adopted.

(1) The helium rapidly becomes pure, so that only slight traces of foreign gases remain, a fall of  $v_{\bullet}$ occurs to a minimum, and the properties of the gas then remain almost constant

(2) The gas layer on the surface of the cathode undergoes slow change, probably by evaporation of the surface gas molecules into the helium and final disappearance in the charcoal This slow change of the cathode surface diminishes progressively its photoelectric emissivity, and increase of  $v_c$  occurs until the modification of the cathode has attained equilibrium

under the existing conditions.

It was determined, for various pressures, that throughout this region the graphs showing the relation between the corresponding values of  $v_c$  and P were smooth curves, and the relation between  $\log~1/P$  and  $v_{\rm e}$  was either linear or of slightly curved form. The quantitative agreement with the equations given in the above mentioned paper was good. We may conclude, therefore, that the results give strong evidence in favour of the photoelectric theory of sparking potentials.

JAMES TAYLOR.

# Sub-Grain Boundaries in Nickel.

Referring to the communication of Messrs. C. J. Smithells and H. P. Rooksby in Nature of Aug. 13, p. 226, concerning their own and Mr. F. S. Tritton's observations on sub-grain boundaries in tungsten

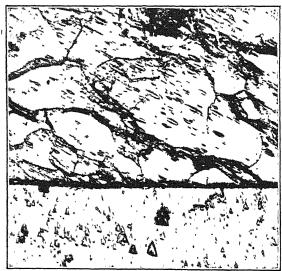

Fig. 1 —Photomicrograph of nickel, deeply etched in concentrated mitric acid.  $\times 200$ 

and iron, it may be of interest to record that we have observed a similar structure in nickel, as illustrated in the accompanying photomicrograph (Fig. 1). This particular specimen was melted in an atmosphere of hydrogen, cooled rather slowly until below the solidification point and then somewhat more rapidly to room temperature.

The micrograph shows portions of two large grains, with a main grain boundary running parallel to one

Sub-boundaries may be edge of the photograph seen in the upper grain Deep etching has resulted in a number of etching pits which are seen to be uniformly oriented within the main grains, thus confirming the observations mentioned above will also be noted that the sub-grams have a slight elongation (suggestive of cold-working) parallel to the direction of the etching pits E. S. DAVENPORT

Westinghouse Lamp Co, Bloomfield, NJ, Aug 25.

#### Poor Common Salt!

' Some books are lies frae end to end," says Burns. Scientific (save the mark) speculation would seem to be on the way to this state! Thus on p 405 of NATURE, of Sept. 17, in a letter on Prof Lewis's light corpuscles, the statement is made by the writer, that a 'speculation,' by Prof. Lewis, about the quantum, "is repugnant to common sense." Again, on p 414, Prof. W L. Bragg asserts that "In sodium chloride there appear to be no molecules represented by NaCl The equality in number of sodium and chlorine atoms is arrived at by a chess-board pattern of these atoms; it is a result of geometry and not of a pairing-off of the atoms"

cricket. Chemistry is neither chess nor geometry, whatever X-ray physics may be. Such unjustified aspersion of the molecular character of our most necessary condiment must not be allowed any longer to pass unchallenged. A little study of the Apostle Paul may be recommended to Prof. Bragg, as a necessary preliminary even to X-ray work, especially as the doctrine has been insistently advocated at the recent Flat Races at Leeds, that science is the pursuit of truth. It were time that chemists took charge of chemistry once more and protected neophytes against the worship of false gods at least taught them to ask for something more than chess-board evidence.

HENRY E ARMSTRONG.

# Solution of the Equation sin $\theta/\theta = c$ .

An approximate solution of the equation  $\frac{\sin \theta}{\theta} = c$ , where  $c \longrightarrow 1$ , may be got in the following manner. By putting  $\sin \theta = y$ , transform the equation to  $\frac{\sin^{-1}y}{y} = \frac{1}{c} = K$  say. The approximate solution of this equation is given by  $y_a = 8\frac{\sqrt{(3K-3)(3K+5)}}{(3K+1)^2}$  which can be evaluated by logarithms Using  $\sin \theta_a = y_a$ , we can find  $\theta_a$ , an approximate solution of  $\frac{\sin \theta}{\theta} = c$ . If  $\theta_a$ be in the neighbourhood of 5° we subtract 1" to get the answer to the nearest second  $\,$  If  $\theta_a$  be less than about 3°, the value of  $\theta_a$  will give us the answer to the nearest second.

In any case, the significant figure of the error (E) may be got by using  $E = \frac{3\epsilon}{A} \left( -\frac{1}{2} + \frac{1}{Ay_a^2} \right)$  where

$$\epsilon = \frac{(\sin^{-1}y_a)^5}{4|5}, A = \frac{3K+1}{4}$$

 $\epsilon = \frac{(\sin^{-1}y_a)^5}{4 \mid 5}, \ A = \frac{3K+1}{4}.$  The true value (y) can then be got by using  $y_a - y = E$ . V. Naylor.

No. 3022, Vol. 1201

# The Safety in Mines Research Station near Buxton. By Prof H. B Dixon F.R.S.

IN moving the Mines Experimental Station from Eskmeals, on the Cumberland coast, to Harpur Hill, near Buxton, the Safety in Mines Research Board has sought and has found an equally secluded site in a more accessible district The choice of such a site in the England of to-day is no easy problem. It must be near a railway so that a siding can be run into it, it must be near a water supply; it must not be near houses or a main road, or indeed near any public path, and, if possible, it must not interfere with the amenities of the neighbourhood Among the sandhills of Eskmeals there was seclusion enough, and the gunrange of Messrs Vickers on the adjoining site afforded both access by rail and immunity from complaint of 'explosion-shock.' But Eskmeals

had two drawbacks; it suffered from sandstorms often, and from inaccessibility at all times

Though hidden by the folding hills, the station at Harpur Hill can be reached in about ten minutes from Buxton, whence lighting gas and water are obtained. The site comprises more than 400 acres and gives a wide 'danger area' on either side of the steel explosion galleries Indeed, the site of the galleries was used for testing guns and various bombs during the War; the nearest works, adjoining the site, are limestone quarries where blasting is constantly in operation.

While the scientific instruments at Eskmeals on the seashore suffered from sand and

salt-spray, the high level of Harpur Hill (1200 feet above the sea) may expose the workers to greater extremes of weather. Great care, however, has been taken to afford protection to the instruments installed, and the observation-huts and experimental chambers are substantially built in concrete.

The two largest buildings on the site may be described as the Administrative Block and the Machinery or Works Block The first contains a row of offices for the staff, flanked at one end by a conference and lecture hall, and at the opposite end by a large laboratory and dark rooms for research work.

Facing these offices the large works building is erected. It is rectangular in form with a central corridor—through which the light railway runs. On one side are the store-rooms, the machine shop, and the blacksmith's shop; on the other side are the battery-house, the power-house, the joiner's and the electrician's shop. There is also a canteen and a cook-house, and ample lavatory and bathroom accommodation for the workmen, as well as arrangements for drying clothes. From the power-house electric current is supplied to the various centres by two circuits—at 110 volts and 220 volts.

For the transport of heavy material a siding

has been run from the High Peak line (L M & S. railway), and material can be unloaded here on to a concrete platform or into the waggons of a 3-feet-gauge railway by a cross-travelling gantry crane spanning the siding and the unloading platform. The 3-feet railway runs to the works block and to the various research buildings on the site; it also runs along the full length of the steel explosion galleries

# THE EXPLOSION GALLERIES.

The longer gallery, 1008 feet in length, is made up of 40 sections of mild steel tubing 4 feet in diameter and  $\frac{5}{8}$ -inch thick. These sections are bolted together gas-tight by means of broad flanges compressing asbestos and wire-rope packing.

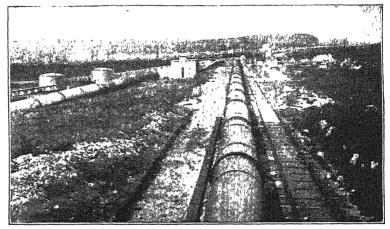

Fig. 1 — View from a bridge across the middle of the 4-ft gallery Reproduced from Paper No. 34 of the Safety in Mines Research Board by permission of the Controller of H M. Stationery, Office

These packing rings simplify the removal of any section, and permit the insertion of a restriction plate at any of the junctions. To prevent distortion of the tube by jumping or 'whipping' during an explosion, each section is bound down on to its concrete cradle by two steel bands anchored into the solid rock below. While the southern end of the gallery is open the northern end is closed, but connects at right angles through a moveable valve to the drift leading to the fan-house. The ventilating fan can create an air current in either direction through the gallery of 1200 feet per minute. A view of the 4-foot gallery is shown in Fig. 1, with the fan-house in the distance and the larger  $7\frac{1}{2}$ -foot gallery on the left

The object of the long gallery being the study of the nature of a coal-dust explosion as it is developed and progresses through its various phases, much care has been expended on obtaining exact records of the passage of the flame and the degree of pressure exerted at fixed points along the gallery. To secure these records instrument-cabins have been erected every 100 feet. They are built of steel plates on concrete foundations; they are close to, but are not fastened to the gallery.

In each cabin a horizontal strip one foot wide has been removed, so that the instruments may be placed on shelves directly attached to the gallery, therefore as the gallery moves longitudinally with changes of temperature the shelves and their instruments travel with it without any strain. To read the pressures developed in the gallery the U.S. Bureau of Mines manometer has been adopted. In this instrument (shown on its shelf in Fig. 2) the pressure acts through a short tube on a cast-

one side of the sensitised paper, which shows the duration and intensity of the flame, and also indicates if periodic vibrations of flame have been set up. Each manometer is separately calibrated by subjecting it to known pressures after each series of tests. The manometer records are finally read on a special drum through a low-power microscope fitted with cross-wires.

For measuring the speed of flame along the gallery, bronze plugs are arranged to screw into

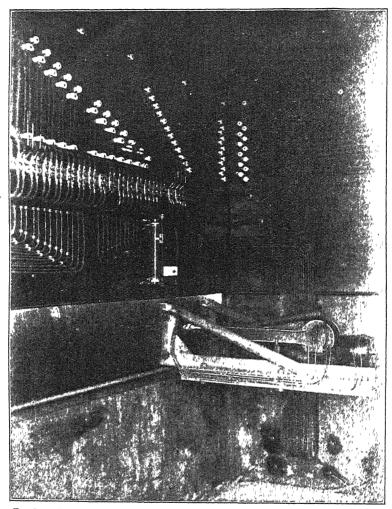

Fig. 2.—4-ft explosion gallery. Interior of No 5 instrument cabin, showing distribution of electric circuits and method of mounting manometer.

Reproduced from Paper No. 34 of the Safety in Mines Research Board by permission of the Controller of H M Stationery Office.

steel diaphragm, the movement of which is communicated to a small concave mirror of stainless steel focussing, a point of light on to a rotating drum carrying sensitised paper. The arrangement is such that the movement of the diaphragm is magnified 150 times in the displacement of the light image on the drum, the speed of which is registered electrically on a chronograph at the firing-station. In addition to acting as a manometer, the instrument also serves to register the passage of flame past a small thick glass window fixed in the side of the gallery. The light, when the flame illuminates the window, is focussed on

the roof at intervals of 100 feet. They carry insulated steel rods 3 inches long, between which are stretched fine-gauge tim wire—to be fused by the flame, but not broken by a pressure wave. In each cabin are arranged the electrical switches to connect the flame circuit-breaker to the chronograph in the firing-station (Fig 2).

# THE LARGE AND SMALL GALLERIES

The  $7\frac{1}{2}$ -feet gallery, a portion of that used at Eskmeals, has been erected for a length of 400 feet, and will be employed for demonstrations of the explodibility of pure coal-dust when it is raised

in a cloud in air and ignited. This gallery will also be used for other large-scale experiments—for example, to determine the distance to which the flame of an explosion of fire-damp is projected along a gallery. For this latter investigation 50 feet of the gallery is separated from the rest by a sliding shutter, which can be opened when the methane and air in the 50-feet chamber are thoroughly mixed. The distance travelled by the projected flame is measured by the burning of thin sticks of cordite attached to the roof every 10 feet in the open gallery beyond

Parallel with the large gallery the 1-foot tube, 300 feet long, is formed of sections bolted together by means of flanges—the joints being made airtight by asbestos rings. Between any two sections a steel 'restriction-ring' can be inserted in order to diminish the diameter of the tube and produce reflexions and turbulence

The gas and air can be circulated and thoroughly mixed by means of a fan and a by-pass tube running

the whole length of the gallery This tube will be used to study the development of fire-damp explosions as the flame travels forward, both when the bore is smooth and uniform and also when the flame meets with surfaces which reflect pressure waves or cause turbulence by forcing the flamefront through smaller openings. Such restrictions, when tried on a small scale, have been shown to have remarkable effects on the travel of an explosion flame, the 1-foot tube will give the means of studying gas explosions with a larger volume of gas and a greater run' of flame than is possible in a laboratory experiment.

#### HIGH-EXPLOSIVES RESEARCH.

One of the most interesting of the new buildings is that devoted to research on the nature of the shock and flame produced by high explosives.

Plant has been installed to photograph by the Schlieren method the progress of the shock-wave through air, and also to record the movement of the flame and of the products of combustion when a high explosive is defonated in a cannon. A large concave mirror of stainless steel focusses the light from an arc lamp on to a moving film across the path of the shock-wave which refracts the beam. The movement of the pressure-wave is thus recorded in the wave-speed camera, which also serves to photograph the motion of the flame itself and of the products of combustion. The speed of the shock-wave in front of the flame, and its gradual dying down as it spreads in free air, are recorded and timed. The conditions for blanketing the flame by the burnt gases of the explosion—a sure protection against fire-damp ignition—can thus be investigated.

For the testing of explosives to be used in coalmining a steel gallery 60 feet long and 6 feet in diameter has been erected. One half of this is the gas chamber, separated from the other half by an oiled-paper diaphragm, and with a central opening at the other end 12 inches in diameter. When the gun is charged it is run up on rails so as to cover this opening—making a tight joint by means of a rubber-washer fixed round the rim of the opening. The methane (or other gas) is filled into the chamber through a meter, and the gas and air are thoroughly mixed by a circulating fan and a bypass tube. The flame can be watched through two thick glass windows in the side of the gas-chamber from an observing station 60 feet away

#### GOB-FIRE RESEARCH CHAMBER.

Another novelty is the structure (of reinforced concrete) to be devoted to the study of gob-fires. The building consists of a central chamber 30 feet square and 8 feet high, simulating a mine goaf, with a passage 6 feet wide running round it. Between the central chamber and the passage are three openings with steel sliding doors operated

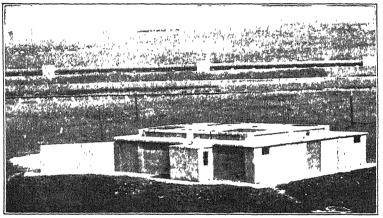

Fig. 3 —The chamber for research on gob-fires — In the background is the 1-ft gallery and beyond is a portion of the long 4-ft gallery.

Reproduced from Paper No. 34 of the Satety in Mines Research Board by permission of the Controller of H.M. Stationery Office

from outside the building. A fan is arranged to deliver a current of air into the passage, and this can be distributed as desired through the goafchamber, into which fire-damp can also be introduced by pipes in the floor leading from a gasholder. Two control cabins are built against the outer wall, and in these the temperature of any part of the inner chamber can be read off from thermo-couples fixed in metal sheaths, and samples of air and gas can be collected from positions either in the coal heap or outside it by means of 4-inch metal pipes protected from fouling by filter-caps fitted to the inner ends. The design of the building (which is illustrated in Fig. 3) is to determine the limiting conditions necessary for the production and ignition of an explosive gas mixture behind a stopping, and to study the methods of sealing off a fire so as to avoid the danger of such conditions arising.

The slow-smouldering of coal-refuse in the goaf has often led to fires, difficult to extinguish, and dangerous because of the inflammable gas distilled from the heated coal. But the conditions under which such gas becomes dangerous are at present little known, and they demand skilled investigation.

# The Englishman of the Future.1

By Prof F G PARSONS.

T has been borne in upon me, little by little, that some of the characteristics of the Englishman of to-day do not seem to be hereditary at all, and that in some things we, in our development, are not following any Mendelian laws, nor are we harking back to Long Barrow, Bronze Age, Celtic, or Saxon types, but that gradually we are building up a new kind of man, differing in certain ways from all of these.

Feeling sure that a change is coming over our younger generation, let us try to see where it is leading, and whether heredity or environment is taking the greater share in guiding it, though we shall surely be wrong if we allow either of these great influences to leave our minds for a moment I must be careful not to undertake more than I can carry through in my time, and therefore I will only ask you to let me say a little about the three physical characteristics of stature, coloration, and head shape, in order to see whether anything may

be learnt from these

I suppose that no one would dare to say what the average height of the modern Englishman is, because we have no State-controlled and State-aided means of sampling the physical conditions of our population in any way. I can state at first hand that the men of our labouring and agricultural classes in the Chilterns average 5 ft. 6 in., and that the mixed classes in a North Kent doctor's practice are 5 ft. 7 in.; but what we do not know is how much the stunted millions in the Midland manufacturing towns, and the mass of unemployed and unemployable humanity in the east of London, will pull this down. I suppose that, taking these into consideration, the average height of the Englishman to-day is not more than 5 ft. 5 in; though when we speak of the well-nourished classes there is a different tale to tell. I know, for example, that for the last twenty years my students at St. Thomas's Hospital have averaged 5 ft 9 in. and in no single year have they ever risen so high as 5 ft. 10 in. or dropped below 5 ft. 9 in.; but, steady though their average at this height has been for twenty years, I am quite sure that they are taller than were my own contemporaries forty years ago, just as those contemporaries, in their turn, were probably taller than the originals of Bob Sawyer's and Ben Allen's fellow-students, who walked the Borough hospitals nearly a century ago.

I think, therefore, that hygiene and better nutrition have done their work so far as stature is concerned. It may be that the more intensive health crusade of the last two or three years may cause a new rise in stature which has not yet had time to show itself, but I can see no signs of it as yet may be, too, that, though environment may have played its last card, heredity may not have done so, and that if for any reason the individuals with a higher percentage of Nordic traits in their patch-

No. 3022, Vol. 1207

work composition are put in a more favourable position to marry and beget offspring than those with a large number of Alpine and Mediterranean traits, the stature may rise still further.

I feel sure, however, that there is a certain average height beyond which the purest Nordic stock will not rise, and my belief is that this has been reached, or nearly reached, already—so far

as the higher classes are concerned.

We have learnt how to raise our male stature to a point beyond which it will not go, and beyond which it is not well that it should go. But what of the woman? About twenty years ago I measured the height of some 150 students of the School of Medicine for Women, and found their average to be 5 ft. 3 m., but after ten years their successors had added a fraction over an inch to their stature; while this year I have measured 150 nurses and massage students at St. Thomas's Hospital, whose

average height was 5 ft. 4.9 in Now these girls belong to the very same class of the community as the male medical students; indeed there are brothers and sisters in the two groups, and the difference with which they have reacted to altered conditions is interesting; for, whereas the boys had reached their full average of 5 ft 9 in. when first I measured them twenty years ago—and their successors, year by year, have never added anything to, or lost anything from, their height, up to the present—their sisters have gained very nearly 2 inches in the twenty years, and practically have reached the height of the average Englishman, whom we dare not estimate as measuring more than 5 ft 5 in. There are no signs, moreover, that these healthily nourished girls have reached their maximum, as have the

One often hears that the English people are becoming darker. To me the simplest index seems to be gained by adding half the number of the intermediate eyes to the light and half to the dark, and by then taking the new percentage of dark eyes as the index of eye coloration. In most cases it is unwise to use the hair or eyes alone, but to combine the two into a general index of nigrescence by adding the indices of the hair and eyes together

and then dividing the sum by two.

I must be content, at this stage, simply to give some massed results in trying to solve the question whether Londoners, who practically are southern English people, have grown darker or fairer during the last sixty years.

The following table gives the material which I have:

	AI	OULT MALES.			
1860 1927	Hair Index 39.7 (2400) 27.4 (1485)	Eye Index. 35.7 (2400) 33.2 (1485)	Nigrescence Index. 37.7 (2400) 30.3 (1485)		
Adult Females.					
$\frac{1860}{1927}$	42.7 (2813) 23.9 (1487)	40 7 (2813) 35 3 (411)	41·7 (2813) 29·6 (949)		

<sup>&</sup>lt;sup>1</sup> From the presidential address to Section H (Anthropology) of the British Association, delivered at Leeds on Sept 2.

BOYS (8 TO 16 YEARS OLD)

1927 8.7 (2565) 33 1 (2565) 20 9 (2565)

GIRLS (8 TO 16 YEARS OLD).

1927 11.0 (1922) 34 3 (1922) 22.6 (1922)

On looking at this table one cannot fail to be struck by the increase in fairness, particularly in the hair; but I do not wish to press it too far, because there are so many possible sources of error. Not only is there the possibility that Beddoe and I had a different border-line between brown and dark brown hair, but other things, such as the modern habit of wearing the hair short, the habit of more frequently washing the head, and the disuse to a considerable extent of pomatum and grease, all give an appearance of fairness which was wanting sixty years ago In the eye records I place more faith, for both Beddoe and I used an intermediate group between the light and dark eyes, a group which I have divided in both sets of records equally between the light and the dark. The drop in the darkness here is not serious, but I think that it is large enough to be significant.

The children's records at first seem irrelevant, since I have nothing of sixty years ago with which to compare them. Their use is to supplement the present-day eye colours of the adults, especially those of the women, which are very scanty. It will be noticed that in children of eight to sixteen the eye colours have become permanent, though the hair has not, and thus their evidence is valuable.

These records, which run into several thousands, do not give us any reason to think that the Londoner is becoming darker, but do give us reason, though it may need discounting, to believe that he is growing fairer under changing conditions.

The last point to which I wish to direct attention is head shape. The anthropologist usually thinks of skulls in terms of their length and breadth, and certainly he has gained a great deal of useful information in the past from this cranial index; lately, however, he has felt that something more is needed, and specialists in craniology have piled up a mass of arcs, indices, coefficients, and angles reason why the cranial or the cephalic index is not enough is that it treats the head as if it were a structure of two, instead of three, dimensions To use a homely simile, it is like giving the length and breadth of a box and then expecting the hearer to grasp what that box is like. We have hundreds of thousands of records of the length and breadth of heads, but very few of their height. I submit that, if we use all three dimensions—length, breadth, and height—together, a standard will be gained which roughly will represent the size of the skull, and with this each dimension may be compared, and a proportional index for each established. The most accurate method, no doubt, is to take the product of the three dimensions and then to extract the cube root and multiply it by three. The result of this is a standard by which the length, breadth, and height of the skull may be divided, and in this way proportional indices obtained which will bear a definite relation to the size of the skull.

Unfortunately the process, though soon learned, is tiresome and needs a logarithm table, which is not always to hand.

A much simpler, and for all practical purposes an equally valuable method of gaining proportional indices, is to add together the length, breadth, and height of the skull, and then to divide each dimension by the sum thus obtained. This gives a series of indices which are, on an average, 0 006 lower than those which the cube-root system supplies; but in no case does this alter the relative position of any of my series of British skulls.

We are fortunate enough to have two independent sets of measurements of the three main stocks which went to the making of the Englishman—the Mediterranean, represented by the Long Barrow or Neolithic Race, the Alpine, represented by the Beaker Folk; and the Nordic, represented by the Anglo-Saxons. One of each of these three sets has been measured by myself, and the other has been measured or collected by Mr. Morant, who published them in Biometrika—If we add the proportional indices of the three stocks together and divide them by three, the result is as follows:

			Length	Breadth	Height	
Morant Parsons	:	•		$\begin{array}{c} 0.3200 \\ 0.3210 \end{array}$		=1 0000 =1 0000
Mean	•	,	0.4195	0.3205	0.2600	=1 0000

This result, surely, is as close as two people working upon different samples and different numbers of skulls of the same races could be expected to reach; and there is every reason to believe that the mean between the two sets of results is more likely to be nearer the truth than either of them taken separately, and ought roughly to represent what we should be likely to find, in the descendants, if equal numbers of Long Barrow folk, Beaker folk, and Anglo-Saxons were mixed and allowed to interbreed.

Let us compare this with the records of the Northamptonshire people who lived at Rothwell in the fourteenth and fifteenth centuries:

	Length	Breadth	Height	
Mean of Long Barrow, Beaker, and Saxons Rothwell Hythe	0·4195	0 3205	0·2600	= 1·0000
	0 4180	0 3230	0 2590	= 1·0000
	0·4090	0·3300	0 2610	= 1·0000

This shows that if we evolve the kind of skull which a mixture of the three main stocks which we know went to the making of the medieval Englishman would produce, we get a form which, in its proportional length, breadth, and height is almost identical with that found in the Midlander of the Middle Ages

When, however, the Hythe crania are compared with these, we see at once that they must have had a different parentage; and what that parentage

is becomes plain when they are placed in company with the Beaker folk

	Length	Breadth.	Height	
Hythe Mean of Morant	0 4090	0.3300	0.2610	=1 0000
and Parsons' Beaker Folk	0 4035	0 3325	0 2640	=1.0000

It seems to me clear that these Hythe people, in the fourteenth and fifteenth centuries, were the result of an incursion and settlement of people from the Continent, of the Alpine Race, who had been slightly, but only slightly, modified by mixture with the Kentish folk

In the eighteenth century the Londoners who lived in the neighbourhood of Clare Market had skulls the proportional dimensions of which differed very little from those at Rothwell:

	Length	Breadth.	Height		
Rothwell Clare Market .	0·418 0·421	0 323 0·322	0·259 0 257	= 1 000 = 1 000	

Apparently, however, there was a little more of the Nordic and a little less of the Alpine element about them.

In the seventeenth century three series of plague skulls are available and were described by Macdonell and Hooke. They are remarkable for their low vaults and receding foreheads, and it has been suggested that they show that the modern Londoner has reverted to the Early Iron Age type, though formerly Pearson regarded them as Long Barrow in their characteristics. Unfortunately we know very little of the craniology of the Early Iron Age. We must therefore let this suggestion stand over until more work has been done upon the head shape of the Iron Age. There is one point, however, which I think should be borne in mind, especially since the Londoners seem to have gone back to a more normal head height in the eighteenth century; it is that during the plague the better class of citizens fled from the city, leaving the dregs of the population behind, and it is in these dregs that receding foreheads and low cranial vaults are most likely to be found. I cannot think that it is wise to use plague skulls as types of seventeenth-century Londoners as a whole.

Now we come to a new and striking development. Until the eighteenth century, the only skulls which show a proportional auricular height of more than 0.260 are those belonging to the Alpine Race, that is to say the Beaker Folk and the Hythe people. Bearing this in mind, it is interesting to notice that in the early nineteenth century the proportion of the head height of English soldiers was 0.262, while in the men of the Royal Engineers, measured by Benington in the early part of the twentieth century, it had risen to 0.267, and in the patients at St. Thomas's Hospital in the present day it is 0.271.

These last three examples are of the less welleducated classes, and even in these it is remarkable

how the proportional height of the head has risen well above anything which any of our ancestors can show, even were we to claim the Beaker Folk as our main ancestors, which all the evidence tells us would be unjustifiable.

When we come to measure the educated classes of the community, which have enjoyed a greater share of the modern, improved conditions of environment, the result is still more striking, for we see the members of the British Association with a proportional head height of 0 271, the St. Thomas's Hospital students with 0 272, the Oxford undergraduates with 0 272, a number of British anatomists who met in Dublin in 1898 with 0 275, and the University College staff with 0 278.

I can see no signs of heredity or harking back to any known ancestry in the change which is coming over the English head, but only signs of reaction to

we ought to know.

over the English head, but only signs of reaction to environment. Is it not reasonable to think that, as the improved conditions of life are gradually shared by all classes, this change in the head shape will gradually become more general until the Englishman of the future is a man with a very differently proportioned head from that of any of his ancestors? I do not wish to decry the old cranial index; it has helped us much in the past, it will help us much in the future. All that I would say is that unless we take the proportional height into account we shall miss a great deal that

To sum up, I am left with the belief that the Englishman of the future is, if present conditions persist, making for an average height of 5 ft. 9 in., and the women for one of 5 ft. 6 in. or 5 ft. 7 in. That our people have reached, and are stationary at, a stage in which some 66 per cent. have light eyes and some 34 per cent. dark. That there are no signs whatever that the hair colour has darkened during the last sixty years, though there are signs, which perhaps need discounting, that the hair is lighter than it was sixty years ago. That the head shape is showing unmistakable signs of an increase of its proportional height, with a decrease of its proportional length, and that this increase of proportional height is greater than has been found in any of the stocks from which the modern Englishman is derived. It therefore cannot be looked upon as a harking back to any ancestral form, but must be regarded as an evolutionary process, in harmony with the greatly changed conditions of life which have come about during the last century.

After all this suggestion, which a study of the head height presses upon us, is one which many have held for a long time. If we accept it I fear that many of the sentimental attractions of British anthropology will be lessened, since there will be greater difficulty in determining whether the modern Englishman has more Saxon, Neolithic, Alpine, or Iron Age blood in his veins; and we must realise that he is becoming an individual who could not be formed by any possible combination of these stocks without the aid of external influences. Heredity alone, therefore, will not account for the Englishman of the future.

# Cave Painting from Griqualand East.1

By Dr Sidney H Haughton

THE large slab covered with paintings, a portion of which is reproduced herewith (Fig. 1), has a height of 3 feet and a length of 7 feet 10 inches It is obviously incomplete, and forms but part of what must have been a larger mural painting

The slab, which is in the collection of the South African Museum, was obtained for the Museum in the year 1912 by Mr G S T Mandy He disThe painting is probably one of the finest of its kind hitherto found in the Cape Province, and is remarkable not only for the coloration but also for the attention paid to details. The nature of the polychrome colouring can be compared with that of the wall-paintings of Altamira

The scene depicted is that of a herd of elands surrounded by hunters armed with bows and arrows

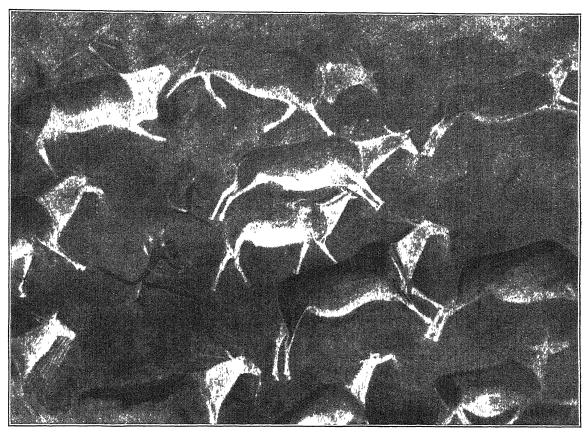

Fig. 1 —Part of polychrome painting on the Zaamenkomst slab Scale about one-sixth natural size.

covered it in a cave on the farm Zaamenkomst, which lies about 12 miles from the town of Maclear in Griqualand East. The slab was lying, in two parts, face downwards, in ash which covered the floor of the cave, and must have fallen either forwards from the wall of the cave or downwards from the roof. There is no evidence available to settle this point. From the ash and debris on the floor of the cave no artefacts or other evidence of occupation have been recovered. No traces of paintings were found on other large slabs which lay in the ash, but on the walls were remains of other scenes showing an entirely different technique.

and also with battle-axes. The hunters are running rapidly, this impression being conveyed by a conventional drawing of the outstretched legs. The animals are depicted as foaming at the mouth, and, in one instance, approaching death is indicated by the presence of bloody foam. The details of the animal figures are far more realistic than those of the men; but the presence of head-plumes and battle-axes as part of the equipment of the hunters lends peculiar interest to the scene, for these would seem to indicate that the men were not Bushmen but Bantu. The late Dr Péringuey considered that the bows and arrows depicted are of the type used by the Barotse and other Zambezi tribes.

<sup>&</sup>lt;sup>1</sup> Reprinted from a paper entitled "Note on the Zaamenkomst Slab" in Trans Roy Soc South Africa, vol. 14, part 3, 1927.

# Obituary.

SIR ARTHUR EVERETT SHIPLEY, G B.E, FRS IT is impossible for me to write without a profound sense of personal loss on the death of the first of the new scientific friends whose acquaintance I made as a freshman at Cambridge in the Michaelmas term of 1880, and with whom I was closely associated during the next twenty-eight Shipley obtained a first class in the Natural Sciences Tripos of 1882 (Part 1) and 1884 (Part 2), and his scientific contemporaries included Adami, Bateson, Chree, Fitzpatrick, J R. Green, Harker, Head, Sherrington, Threlfall, and D'Arcy Thompson In the interval between the two parts of his Tripos he had spent several months at the Zoological Station at Naples, the results of his studies being contained in his first scientific paper, on Brachiopoda (Argiope) He did not specially follow up this line of investigation in later years, but his continued interest in the subject is shown by the fact that he wrote articles on Brachiopoda for "The Cambridge Natural History" (1895) and the "Encyclopædia Britannica" (1902)

The atmosphere of Cambridge in Shiplev's undergraduate days was eminently calculated to encourage and stimulate the imagination of pupils who were ready to take an interest in science. Liveing, Humphry, and Michael Foster had been mainly instrumental in establishing the claims of natural science to an honoured place in the University. Lord Rayleigh was Cavendish professor, and zoology was represented by Alfred Newton as professor, supported by J. W Clark in charge of the Museum, and by F. M. Balfour and Sedgwick at the laboratory. Vines, a member of Shipley's college, was engaged in teaching botany on modern lines. Balfour had given a great impetus to the study of embryology; and his personal qualities, no less than the scientific eminence he had achieved, endeared him to his pupils in a way few teachers are beloved. The news of the Alpine accident in 1882, which cut short his brilliant career in early life, was, I think, first broken to me by Shipley, and it produced on us a supreme consciousness of personal grief. Balfour's example had had its influence, and Shipley took up the study of vertebrate embryology, producing, in 1887, a memoir on the development of the lamprey. Soon afterwards he turned his attention to the Gephyrean worms, an interest which he maintained for many years, his first substantial paper on this subject having appeared in the Quarterly Journal of Microscopical Science (1890). He afterwards contributed a series of papers on this group to this and other journals, and he described the Gephyrea collected by various expeditions, including those of Prof. Stanley Gardiner to Rotuma and Funafuti and the Maldive and Laccadive Islands, and of Dr. Arthur Willey to the Loyalty Islands and New Britain.

Shipley's interest shifted, in later years, to aspects of zoology which are not merely academic. So early as 1889 he had contributed to the *Kew Bulletin* a note on beetles destructive to rice-crops

in Burma, and he continued to take a special interest in economic entomology, a subject which is predominantly represented in his charming 'Minor Horrors of War'' (1915) and "More Minor Horrors" (1916) He was largely instrumental in the inception, by the Colonial Office, of the Imperial Bureau of Entomology, which was established in 1909, at first under another name, with Lord Cromer as its first charman

A substantial part of Shipley's scientific work was concerned with parasitic worms, with one or two papers on the Pentastomida, curious wormlike parasites which appear to be degenerate Here, too, the practical side of the Arachnida subject made a special appeal to him, as for example in his work for the Departmental Committee on Grouse Disease, and for the report to the Ceylon Government on the pearl oyster fisheries His sense of humour was stirred by the reflection that a lady wearing a pearl necklace is usually not aware of the fact that the production of a pearl may have been due to the effort of the mollusc to protect itself against a young intrusive tapeworm.

In 1893, Shipley produced his "Zoology of the Invertebrata," a text-book which has been largely used by students; and he collaborated with his friend Prof. MacBride in the preparation of another text-book ("Zoology"), which appeared in 1901 and has had an equally successful career. He had previously been associated with Dr. Schonland and Prof. Poulton in issuing as an English translation Weismann's "Essays upon Heredity," a work which greatly assisted in familiarising English readers with Weismann's work He was joint editor of "The Cambridge Natural History," which appeared in ten volumes from 1895 to 1909, and editor of the Pitt Press Natural Science Manuals (Biological Series) and of the Fauna of British India Series. He was perhaps at his best as a popular exponent of zoology His writings in this capacity, in the columns of the Times and elsewhere, abound in humorous touches which give them a specially readable and attractive quality, and they include many acute observations made by himself during his numerous journeys to the United States and other parts of the world

Shipley was born at Datchet on Mar. 10, 1861, and was educated at University College School and for a short time at St. Bartholomew's Hospital He entered Christ's College, Cambridge, in 1880, and became successively Fellow and Master of his College and Vice-Chancellor of the University He took a substantial part in lecturing, and for many years he was secretary to the Museums and Lecture Rooms Syndicate, a position involving the practical management of many of the affairs of the numerous buildings under his charge His capacity for work was unlimited, and he did very notable service to his College and University, and to the country generally, particularly during the years of the War. As early as 1887 he was sent by the Colonial Office to the Bermudas to investi-

gate a plant disease, and late in life he was specially concerned in the establishment of the Imperial College of Agriculture in Trinidad, which he visited on more than one occasion and of which he was chairman He was also chairman of the Council of the Marine Biological Association, a member of Royal Commissions on the Civil Service, Trinity College, Dublin, and the importation of store cattle and of the departmental inquiry into grouse disease, and he was a trustee of the Hunterian, Tancred, and Bert Foundations His scientific distinction was recognised by honorary degrees conferred on him by Princeton, Michigan, and Philadelphia, and by being made foreign member of the American Association of Economic Entomologists and of the Helminthological Society of Washington, and honorary member of the Société Zoologique et Malacologique de Belgique His period of office as Vice-Chancellor of the University of Cambridge, in 1917–1919, was described by the Times of Sept. 23, in an interesting account of the invaluable services which he performed for the country, fitly recognised by the award to him of the GBE in 1920. He died at the Master's Lodge of Christ's on Sept 22

Few men have had a wider circle of friends than Shipley, whose gifts of sympathy made him

persona grata to all sorts and conditions of men, from cabinet ministers to undergraduates fresh from school He died full of honours and universally respected as a man who consistently maintained the highest standard of public and private duty, and in the midst of responsibilities which might well have absorbed all his attention, was always ready to give his time to the performance of innumerable acts of kindness.

SIDNEY F. HARMER.

WE regret to announce the following deaths:

M Emile Haug, membre titulaire of the Section of Mineralogy of the Paris Academy of Sciences, professor of geology at the Sorbonne and a past president of the Geological Society of France, on Aug. 28, aged sixty-six years.

Prof. L R. Lenox, for thirty-five years a member of the faculty of chemistry at Stanford University,

on July 25, aged sixty-two years.

Dr Thomas W. Salmon, medical director of the US National Committee for Mental Hygiene and professor of psychiatry in Columbia University, New York, on Aug. 13, aged fifty-one years.

Prof. Adrian Stokes, Sir William Dunn professor of pathology in the University of London, while with the Rockefeller expedition investigating West African yellow fever, at Lagos on Sept. 19, aged forty years.

# News and Views.

Manufacturers in Great Britain have been the targets of much deserved criticism on account of their long neglect of the assistance which systematic chemical and physical research is able to offer them, but in recent years their attitude has implied a growing faith. Doubtless their policy in the past has been conditioned more by the fact that research organisations adequate to the study of many of their problems cost a great deal of money than by any hostility to the idea of progress, although this is probably not universally true; 'small profits and quick returns,' however excellent a maxim, does not stimulate the long view when business is brisk, and cannot afford it during a slump. The realisation, however, that industrial competition does not necessarily exclude scientific co-operation has led to the establishment and profitable operation, with State assistance, of a number of research associations. The youngest member of the family is the Research Association of British Paint, Colour, and Varnish Manufacturers, which was incorporated in September 1926, and the laboratories of which were opened at the first annual general meeting at Teddington on Sept. 21

THE new Association, of which the president is Mr. S. K. Thornley and the director is Dr. L. A. Jordan, comes into existence at an interesting, if difficult, stage in the history of paint and varnish making. The ingredients of the good old varnish, often made by a secret process, find themselves challenged by new materials having unchallengeable protective and decorative qualities; the new materials require careful study in a variety of conditions, and the

relation of the character of the protective film to those of the liquid applied are by no means fully understood. It is now realised that the paint or varnish, as manufactured, is, after all, only an intermediate product; its properties are of interest chiefly so far as-subject to the interference of external conditions such as climate and weather—they govern those of the film. Decoration, as well as protection, also moves with the times. The statement that the United States of America is using wood four times as rapidly as it is growing, or that that country wastes thirty million dollars annually on rust and decay, is adequate enough to support the 'more and better paint' movement, but a generally enhanced appreciation of the decorative value of paint coatings, with its demand for new shades of colour, new surfaces, and new properties, cannot be ignored.

CLEARLY, the wide problems of the paint and varnish industries are beyond the resources of single manufacturers. Co-operation, however, has already made possible the equipment for the new research association of three chemical and physical laboratories, with offices and library, and work is now proceeding on the equipment of a workshop and technical laboratory, so that processes can be tested on a semimanufacturing scale. Already several specialised pieces of plant and apparatus have been presented or lent to the Association by firms or individuals interested in its work. Whilst the technical side of the work is in its preliminary stages, laboratory research on several important problems is already in active progress. Economies and profits will doubtless accrue to the promoters from many of the investigations

undertaken, but it must be remembered that a single important property such as the durability of paint may eventually be thereby improved in such a way as to conter benefits on the community and on the individual far greater than can be measured by the financial return to the paint and varnish industry itself. Governments seldom fail to receive their due share of abuse, and politicians are but infrequently immune from accusation of their failure to see, much less appreciate, the scientific point of view, yet much may be forgiven a Department of State which has had Ithe wisdom to encourage, with practical assistance, the policy of co-operative scientific and industrial research, and those various groups of business men who, though times have been bad, have had the foresight to translate the policy into effective action

THE biennial conference of the International Society of Leather Trades' Chemists took place from Sept 12 to 14 at the Leathersellers' Hall, London, and was attended by the president of the Society, Prof D. McCandlish, the Worshipful Master of the Leather-Company, representatives from British sellers' scientific societies and trade organisations, and members of the Society from Great Britain, France, Belgium, Italy, Czecho-Slovakia, Spain, and India. The Conference paid a warm and respectful tribute to the memory of the late Prof. H. R. Procter, the great pioneer of the scientific study of leather manufacture and one of the founders of the Society, and decided in his honour to establish a fund for the endowment of a post-graduate fellowship for research in leather chemistry to be held at the Procter International Research Laboratory at the University of Leeds. The progress of scientific research in the leather industry has constantly been hampered by the difficulty of analysing such complex materials as leather, tanning extracts, and hide, and research in analytical methods inevitably occupies much of the attention of the Society. The methods hitherto recommended by the Society are not trustworthy in their results, and the conference decided to confirm the adoption of the new method for the analysis of tanning materials which was recommended in May last at an international congress of the three societies of leather trades, namely, the International Society, the American Leather Chemists' Association, and the Internationale Vereine der Leder-Industrie Chemiker. This new method has now been adopted by the International and the American societies, and it is believed that the German society is also taking the necessary steps to ensure its adoption by their members.

The basis of the new method which has been recommended by the International Society of Leather Trades' Chemists for the analysis of tanning materials is the use of a hide powder washed free from mineral salts by means of a very weakly acid solution brought to a pH of 5 to 5.4, i.e. to the iso-electric point of collagen. Such powders contain only a trace of mineral matter and give much more uniform results in the analysis of tanning materials than earlier powders, which contained a variable residuum of

calcium salts. The methods of analysis of vegetable and chrome tanned leather and various materials used in the manufacture of leather were also considered at the recent meeting. It was urgently recommended by the Society that the great amount of damage caused by the warble fly should be brought to the notice of the governments of each country represented There are several good specifics against the pest, dichlorbenzoyl in vaseline and a suspension of tobacco powder both having proved effective In Denmark the use of prophylactics had been made compulsory, with the result that the percentage of damaged hides among the indigenous cattle had fallen from 25 to 8 The British Warble Fly Commission, under Prof. Carpenter, abolished warble fly in two years from a small island off the north coast of Ireland. Re-infection of clean areas by imported stock is controlled in Switzerland by the compulsory slaughtering of all imported live cattle within twenty-four hours. In England there are no compulsory measures against warble fly, and live cattle for store purposes enter freely at the ports. It is perhaps not surprising that the percentage of 'warbled' hides among English and Irish cattle is very high.

To the July number of Electrical Communication, Mr. Rollo Appleyard contributes a very interesting article on Charles Wheatstone. Wheatstone is best remembered by electricians in connexion with Wheatstone's bridge, which is used in measuring electrical resistance. Yet curiously enough, Wheatstone himself scrupulously assigns this bridge to its first inventor, S. H. Christie. If it is true that a man is known by his friends, then it is sufficient to mention that Wheatstone was the friend of Faraday, Huxley, Brewster, and Tyndall, all of whom did invaluable work in the cause of science and consequently for the benefit of humanity. With the exception of Brewster, none of these had received what can be called systematic education, but all were enthusiastic research workers Wheatstone, probably more than any other man, developed the practical side of electric telegraphy. No account of a practical electric telegraph was published prior to Cooke's and Wheatstone's patent taken out in 1837. His sine wave model, his kaleidophone, his gas-jet organ, his concertinas, and his polar clock are only a few of his many inventions His rotating mirror verified Kelvin's prediction that in many cases a Leyden jar spark discharge is oscillatory. His endless patience as an experimenter was proved by the many experiments he made to determine the velocity of an electric discharge through a wire. But as J. B. Dumas said, his memory will live not only by his achievements but also by the recollection of "his rare qualities of heart, the uprightness of his character, and the agreeable charm of his personal demeanour."

ONE of Wheatstone's earliest inventions was an instrument he called "the enchanted lyre." It was suspended from the ceiling by a cord and the music appeared to proceed from a combined "harp, pianoforte, and dulcimer." Wheatstone himself described

it as an application of a general principle for conducting sound. A writer in the Repository of Aits for September 1821, when describing this instrument, foreshadows modern broadcasting in a remarkable way. "Who knows but by this means the music of an opera performed at the King's Theatre may ere long be simultaneously enjoyed at Hanover Square Rooms, the City of London Tavern, and even at the Horns Tavern at Kennington, the sound travelling ... from the main laboratory of harmony in the Haymarket to distant parts of the metropolis ... perhaps words of speech may be susceptible of the same means of propagation." In this connexion it is interesting to recall that the ancient Greeks believed that Pythagoras could lecture simultaneously in several towns many miles apart.

In the course of the Congress of the Institut International d'Anthropologie, which was held at Amsterdam on Sept. 20-27, it was announced that the Prix Hollandais of the Institut has been awarded to Miss Dorothy A. E. Garrod in recognition of her work in prehistoric archæology, and especially for her excavation of the cave at the Devil's Tower, Gibraltar, in the course of which she found the second of the two Mousterian Gibraltar skulls, the first having been discovered in 1843. It will be remembered that the site on which Miss Garrod worked was noted by the Abbé Breul during the War, but excavation necessarily had to be postponed. A preliminary account of the fragments of the skull discovered by Miss Garrod earlier in the summer, which had been reconstructed by Mr. Dudley Buxton, was given at the Oxford meeting of the British Association last year. Miss Garrod returned to the site later in the autumn and cleared the cave to bed-rock, discovering further fragments of the skull. The whole, as now reconstructed, apparently that of a child from eight to ten years old, will be exhibited and described shortly at a meeting of the Royal Anthropological Institute. Miss Garrod is also the author of a valuable survey of the evidence relating to early man from the caves in Britain entitled "The Upper Palæolithic Age in Britain." We offer our sincere congratulations to Miss Garrod on her well-deserved honour.

Mr. C. F. Talman, librarian of the United States Weather Bureau, is writing articles on weather topics every day for Science Service of Washington. These are appearing in the Boston Transcript and ten other North American newspapers. The uniquely favourable position of Mr. Talman for work of this kind is evident after a perusal of one of these articles, which gives an account of the library under his charge at Washington. This library contains about 46,000 volumes, and is said to be the largest of its kind in existence; it includes a vast number of books about the weather and climate of all parts of the globe, in addition to all treatises on meteorology that have appeared anywhere in the world, so far as the U.S. Weather Bureau has been able to secure them. With this mine of information immediately to hand, Mr. Talman no doubt has little

difficulty in finding some item of interest for each day of the year; he has, moreover, the gift of being both lucid and entertaining.

THE range of subjects dealt with by Mr. Talman in a sample batch of articles received recently, covering the period May 2 to Aug. 18, 1927, occasionally extends into the borderland of meteorology, e.g., "Experiments with Icebergs"—an account of attempts to destroy icebergs with the aid of ignited charges of thermit—"The Dust we Breathe," "Mysterious Sounds that Haunt the Air," "Will o' the Wisp," and so on Care has been taken to choose, so far as possible, subjects likely to be topical at the time of their publication, which is of necessity a week or so later than the time when they are completed; thus for May 11 an article on "The Traditional Cold Spell in May" was chosen, while several articles on very hot weather, and the best means of avoiding its attendant discomforts, were timed to appear in that portion of July that has the highest mean temperature. It is satisfactory to find no evidence anywhere in the series under review of a sacrifice of accuracy to interest. The articles must stimulate thought and should tend to dispel many absurd illusions about the weather that are still current

THE Registrar-General's Statistical Review, 1926, Tables, Part 2, has recently been issued by H.M. Stationery Office (price 5s.). Among the wealth of material it contains, the following points are of wide interest. The total population in thousands of Great Britain and Ireland was:

	1926	1925	Increase+ or Decrease- per cent
England and Wales.	39,067	38,890	+0.46
Scotland	4,897	4,893	+0.08
Northern Ireland .	1,256	1,257	- 0 08
Irish Free State .	2,970	2,985	- 0 50
Total	48,190	48,025	+0.34

In England and Wales the male population increased by 0.52 per cent. and the female population by 0.40 per cent. The births registered during the year 1926 numbered 694,563, which is equal to a rate of 17.8 per 1000 population. This rate was 0.5 per 1000 below that recorded in the previous year and, with the exception of the War year 1918, is the lowest rate recorded since the establishment of civil registration. Not only has the birth rate declined but also the actual number of births is the lowest recorded since 1860, when the population of England and Wales was only 19,902,000, or about one-half of the estimate for 1926. The number of illegitimate births was 29,591, or 43 per 1000 total births, and was 695 in excess of the total recorded in the previous year. The proportion of male to 1000 female births was 1041. This proportion showed a great increase during the War years and reached a maximum of 1060 in 1919, since when the decline has been almost continuous, and the rate is now approximating to that which prevailed in the period immediately prior to the War.

LATE on the night of Sept 24, the R R.S. *Discovery* anchored in Falmouth Harbour, having completed a two years' cruise to Cape Town, South Georgia, and

the Falkland Islands, she is expected to arrive in the Thames on Oct 1 It will be remembered that the primary object in fitting out the Discovery expedition was the investigation of the southern whaling fisheries, and a report of the work carried out up to August 1926 was contributed by the Director of Research, Dr Stanley Kemp, and members of the scientific staff, to our issue of Oct 30, 1926. p. 628 The first annual report of the expedition, bringing the account up to the end of 1926, has been recently published (see NATURE, Aug. 27, p 308) It is expected that the scientific staff will spend some months ashore working up the results of the expedition, and it is confidently expected that these will prove of great value to science and to the whaling industry

A new speed record was set up near Venice by Flight-Lieutenant S. N. Webster when he won the race for the Schneider Cup for Great Britain on Sept. 26 at an average speed of 281 miles 1246 yards an hour The race was over a course about 31 miles in length and triangular in shape, and seven laps had to be covered; this meant making two sharp turns in each lap. Three Italian and three British machines started, but the Italian pilots and one of the British pilots had to come down Lieut. Webster was flying a Supermarine-Napier S5 with geared engine. This engine, a development of the Napier Lion unit, weighs 920 lb. and develops 890 hp The Supermarine seaplane was designed by Mr. R J. Mitchell, who seems to have been most successful in devising means for reducing head resistance; for example, petrol was stored in one of the floats, while the radiator for the water-cooling system was fitted in an improved way beneath one of the wings. The only other machine which completed the course, piloted by Flight-Lieut O. E. Worsley, was also a Supermarine Napier, but with an ungeared engine Lieut. Worsley's average speed was 2736 miles an hour. In last year's race for the Schneider Cup, the winner, Major de Bernardi (Italy), on a Macchi monoplane with 800 h.p. Fiat engine, averaged 2465 miles an hour. This year, for the first time, the British entry was organised entirely by the Air Ministry and service pilots were trained for the race

To ascertain the value of aerial photography in the revision of 1/2500 Ordnance Survey plans, an area of some fifty square miles near Eastbourne was photographed from the air at the same time that the usual revision was taking place during the summer of 1925. The results of this experiment are given in a small pamphlet issued by the Ordnance Survey and entitled "Report on the Experimental Revision of the 1/2500 Ordnance Survey Plans with the aid of Photographs taken from the Air" (London: H.M. Stationery Office. 4d. net). It was found that this method was 50 per cent. quicker than field work, 1670 square miles being photographed by one machine in less than one hundred days. With the exception of some types of wire fences, all details were easily identified in the photographs, and changes in features could be plotted with accuracy. Invasion of lands and premises is reduced by the new method, and the interval between

revision and publication should be shorter than it was of old. The high costs of aerial ievision could no doubt be substantially reduced, but the speed of the work makes it impossible to offer a continuous programme of flying to the aviators As a result of the experiment, the Ordnance Survey proposes to revise solely by aerial photography an area of about 100 square miles each year for several years. It will then be possible to decide if the method will be economical to adopt for all large-scale revisions.

WITH the object of collecting, correlating, and placing at the disposal of British industry, all information of a technical and practical character with regard to the use of nickel and its alloys, the Bureau of Information on Nickel, Limited, has been established with offices at 2 Metal Exchange Buildings, Leadenhall Avenue, London, EC.3. The services of the Bureau will be rendered without charge or condition

SIR ARTHUR KEITH'S recent presidential address to the British Association is to be published in Messrs. Watts and Co.'s Forum Series. It will contain a foreword and a supplementary paper entitled "Further Evidence and Some Unsolved Problems"; and there will also be included three essays on "Darwin's Home," "Why I am a Darwinist," and "Capital as a Factor in Evolution," as well as a page diagram elucidating man's origin. The price of the publication will be 7d.

Applications are invited for the following appointments, on or before the dates mentioned :-- A lecturer in engineering subjects at the Technical College, East London, South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C 2 (Oct. 7). A woman professor of physiology at the Lady Hardinge Medical College, Delhi—The Honorary Secretary, U.K. Branch Dufferm Fund, care of Major-General J. B. Smith, India Office, Whitehall, S.W.1 (Oct. 8). An agricultural economist and an agricultural engineer under the agricultural department of the Tasmanian Government — The Agent-General for Tasmania, Australia House, Strand, W C.2 (Oct. 14). A county education officer for the Administrative County of Southampton—The Clerk of the County Council, The Castle, Winchester (Oct. 17). An entomologist in the veterinary department of Tanganyıka Territory with special knowledge of the blood-sucking diptera and the Ixodidæ-The Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S.W.1 (Nov. 15). A senior lecturer in geography and geology at the Natal University College, Pietermaritzburg—The Registrar, Natal University College, Pietermaritzburg, Natal (Nov. 30). A woman graduate as chief assistant in the Domestic Science Department of the Battersea Polytechnic—The Principal, Battersea Polytechnic, S.W.11. assistant bacteriologist at the Wellcome Research Laboratories, Khartoum—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, S.W.1. A test assistant at the Aeroplane and Armament Experimental Establishment of the Air Ministry, Martlesham Heath-The Officer Commanding, Aeroplane and Armament Experimental Establishment, Martlesham Heath. Woodbridge, Suffolk An evening lecturer in structural mechanics at the West Ham Municipal College—The Principal, Municipal College, Romford Road, Stratford, E.15

THE Royal Commission appointed by the Commonwealth Government to inquire into the control and development of radio severely criticises Amalgamated Wireless (Australasia), Limited. This Company claims to have many patents, embracing all branches of radio communication. According to a report in the Times of Sept 15, the Commission says that the Company's demand for royalties is based on the principle "that it is entitled to obtain from the public whatever it can get." The Commission urges that the Company should make reductions in the charges for the use of patents If the Company fails to make the suggested reductions, the Com-

mission urges that the Commonwealth Government, after ascertaining that the patents are valid, should purchase all the privately held shares in the company and so acquire complete control Without a full knowledge of the facts, it is very difficult to criticise the motives and actions of the Commission and of Amalgamated Wireless (Australasia), Limited. The Government of Australia holds the majority of the shares, and we should have expected them to control the actions of the Amalgamated Company companies which have expended considerable sums in research for many years hope to reap a harvest later on. It is in the public interest that they should receive royalties on their patents at least for a period of years. It is in this way that great industries have been built up. We believe that there are between two and three thousand companies in Great Britain which utilise broadcasting patents. There seems to be no attempt to create a monopoly for a few favoured firms. The question seems one that could be quickly settled by arbitration

### Our Astronomical Column.

ROTATION OF THE GALAXY -The fact that the spectroscope reveals rotation in several spiral nebulæ renders it not improbable that a similar motion may be present in the galaxy, which has many points of resemblance to the spirals; it is not very easy, however, to detect a small systematic effect of this kind from star observations. Mr J. H. Oort makes the attempt in Bull Astr Inst Neth., No. 132 He makes the assumption that there is unlikely to be any systematic motion at right angles to the galaxy; he therefore deduces the precession from proper motions resolved in that direction and finds a correction to Newcomb's precession of 1".37 per century and a rotational effect of about 1" per century.

Mr. Oort notes that if all the mass of the galaxy were concentrated at the centre, the law of force would be the inverse square of the distance; while if the mass were distributed uniformly through a sphere, the law within the sphere would be the direct distance; the actual law would be between the two. He deduces tentatively that the force according to the inverse square law is 6/10 of the whole, from which he finds that the central mass is about sixty thousand

million times that of the sun.

The linear speed of rotation in the sun's neighbourhood is found to be 286 km./sec. towards galactic longitude 55°. The author suggests that the radial velocities found for the Magellanic Clouds is accounted for by this rotational motion, so that they may be outlying portions of the galaxy.

THE NEW STAR IN AQUILA.—Astr. Nach., No. 5519, contains details of the spectrum of this star as photographed at Konigstuhl by Prof Max Wolf on Aug. 17. These agree well with the usual nova type. The hydrogen lines  $H\beta$  to  $H\eta$  were seen both as emission and absorption lines; the absorption lines indicated a radial motion of  $-1600~\rm{km}$  /sec., while the emission ones indicated +100 to +150 km./sec.

THE TOTAL SOLAR ECLIPSE OF JUNE 29.—Astr. Nach, No. 5519, contains observations of the total solar eclipse made at Ringebu, Norway, by G. Armellini and G. Conti of the Campidoglio Observatory, Rome. Shadow bands were well seen both before

and after totality, the latter being the stronger. They were curved like the letter S and had an undulatory movement. The illumination during totality was much greater than that of the full moon. Signor Armellini could read type 0.5 mm. high, while 2 mm. was the minimum in full moonlight. Most of the light during totality was diffused skylight, not that of the corona, as was shown by the fact that a stick 4 cm. in diameter threw no perceptible shadow on a white sheet. The observed times of beginning and end of totality were 5h 34m 50 3s, and 5h 35m 24.6s, U.T., each about \frac{1}{2} sec. earlier than calculation.

A sketch by Signor Conti shows the corona as a uniform ring some 7' high, with seven long rays at fairly equal intervals. The longest are 40' long. The temperature fell from 11°·1 C. to 7° 9 C., afterwards rising to 12°·4 C. The colour of the prominences is described as reddish-violet and as yellowish-red by

the two observers respectively.

NORMAN LOCKYER OBSERVATORY.—The annual report of the director of the Norman Lockyer Observatory, which has recently appeared, shows a continuance of the programme which has been so usefully followed during the last few years. The chief features are the photography of stellar spectra for classification and parallax work, and the detailed study of changes in the spectra of bright line stars of early type. Four papers dealing with this work have been published during the year, and three others are in preparation. In addition, the 51-inch doublet has been mounted for the photography of meteors, and has been oriented to the pole star on clear nights when there has been no bright moonlight. Arrangements were made for obtaining large-scale photographs of the chromosphere, prominences, and corona, and small-scale photographs of the corona and its spectrum, at Richmond (Yorks.) during the total solar eclipse of June 29 last; while at the observatory at Sidmouth, preparations were made for securing large-scale spectra of the chromosphere with the Hilger Littrow spectrograph. Neither programme, however, could be carried out, owing to unfavourable weather. The accounts for the year show a loss of £227, and the hope is expressed that further endowments will be forthcoming.

# Research Items.

Chinese Gongs.—Major E. C. Kenny, in Man for September, describes the two types of rare 'Chinese gongs' which are found in Burma, and usually called by the English residents there 'Karen War Drums.' They are now only found in the little frontier State of Karenni. The gongs are of two types, and of these the taller and more modern were made up to a time so recent as 1894 by the Shan for their overlords the Karen. The flatter ancient type is beyond doubt of Chinese origin, and is very rare. The Karen assert that these latter were not made by human agency at all, but by spirits, who are said to assume the forms of beautiful maidens and to sing sweetly in the jungle on the outskirts of villages, attracting youths whom they destroy. One gong of this type in the British Museum is dated 'Made by Chang Fu in the 7 month of the 4 year of the reign of Chien Hsing," ie a document to whether they are decorated or not, the latter being the male, and are frequently found in pairs. The drums are used for crop and other festivals, and periodically for summoning the outlying villages, but apparently never for war.

THE STONE BATTLE-AXE.—The spread of the stone or copper battle-axe is discussed by Prof. H. J. Fleure and Mr. Harold Peake in a communication in Man for September. They take the view that the axe-hammer with a shaft-hole was probably first made in metal and that the oldest example published is that from Cemetery A at Kish, dated at 3100-3000 BC., although older examples have recently come from Ur. Although it may seem a far cry from Mesopotamia to a European centre, the connexion between early Kuban and the Cyclades has been demonstrated, while the former has too many elements of kinship with Mesopotamia to leave any doubt of their common origin. It is suggested that it was through the Cycladic contact with Kuban that the battle-axe entered Cycladic Minoan culture in Early Minoan II The early metal axe of copper had the butt end bent round to form the shaft-hole, and the earliest cast specimens had the hole nearer one end. When copied in stone the axe would have one cutting-edge with the shaft toward the butt end, though not so near as in the metal type, to avoid splitting. It has been argued that of the British perforated axes, those with the hole nearer one end are earlier than those in which it is situated centrally. It is agreed that in the Baltic area the stone battleaxe underwent great development, but even here a copper axe from Norway would serve as a metal prototype. The authors' view is that in the Baltic area the only culture was that of the shell mounds until the Megalithic culture impinged on it from the south-west and the culture of the battle-axe and fine flint work came from the south-east.

International Herring Investigations.—Rapports et Procès-verbaux des Réunions, vol. 41, of the Conseil Perm. Internat. pour l'Expl. de la Mer, contains a good deal of information concerning the present state of our knowledge of the herrings in the North Sea, and sets out the programmes of investigations which are being undertaken by the countries interested. The immense value of continuous observation over an extended period is admirably demonstrated by the striking results achieved by the Norwegian investigators through an unbroken series of years from 1907 to the present time. Mr. Einer Lea's preliminary report on these results, and his discussion on the most

satisfactory method of summarising the observations for one season so as to give the best possible representation of the age-composition of the stock, will be read with interest. The report on Scottish investigations regarding the larval and post-larval stages of herring in the northern North Sea not only indicates the immediate difficulties experienced, but also demonstrates the general fact that great caution must be exercised when estimating age from scales of adult Evidence is advanced that some of the Scottish post-larvæ acquire scales during the calendar year in which they are born, so that their first winter of life is recorded on the scale as a winter-ring. Others, however, remain in the unscaled condition until the year following birth, the first winter-ring not being formed on the scale until the second winter of life. This fact very materially adds to the difficulty of estimating the age and origin of the adult fishes which visit Scottish waters.

FISH EGGS AND LARVÆ FROM THE JAVA SEA.-In vol. 8 and vol. 9 (1926) of De Treubia, Dr. H C. Delsman gives a detailed account of his studies of fish eggs and larvæ from the Java Sea. His observations of the time of the day at which spawning appears to occur, and of the length of the incubation period of some of the eggs, are particularly interesting. Thus, the eggs of three species of the genus Caranx are all set free at a definite time towards midnight. 9 A.M. on the following morning, that is, less than 12 hours after, those of C. macrosoma hatch out Between 11 A.M. and 1 P.M. those of C. kurra hatch, while at 6 P.M. the young of C. crumenophthalmus emerge. In the course of egg-sampling with townets, therefore, the eggs of C. macrosoma are to be found only in early morning hauls; those of C. kurra disappear from the tow-nets at about 1 P.M., so that in the afternoon only those of C. crumenophthalmus These results are in accordance with a general rule that larger, more yolk-laden eggs take a longer time for their development than smaller ones with less yolk. Equally striking is the author's account of the growth of the embryo assigned to Clupea fimbriata. Eggs taken at 7 AM. showed only a small germinal disc and had evidently been laid shortly before capture. At 8 45 A.M. the germinal disc had grown half round the circumference of the egg, and the first indication of the embryo had appeared. At 10.45 A.M. the blastopore closed and the rudiment of the embryo had grown more distinct. During the afternoon the tail grew out, the embryo began to 'sprawl' within the spacious egg-membrane, and at 6 P.M. it hatched. Some idea of the speedingup of the incubation period can be gathered from the comparison between the hatching of Scomber kanagurta in less than 24 hours, and that of the mackerel Scomber scomber) in 6 days in British waters, or with the 5 days for the American mackerel.

Japanese Freshwater Branchiofoda.—M Ueno (Mem. Coll. Sci. Kyoto Imp Univ., B, vol. 2, No. 5, art. 12, 1926) gives a list and some details of the genera, species, and varieties of freshwater branchiofoda hitherto found in Japan, together with a few records from eastern China Of the thirty-one species of Cladocera, twenty-five are found also in Europe, but the Japanese Phyllopoda belong to species not represented in Europe. The author is inclined to believe that Japanese examples of the Cladocera are generally smaller in size than corresponding specimens from Europe or America, but he adds that further study is required before this can be decided.

GROWTH OF PARAMECIUM -F. Mizuno has made careful observations (Science Reports, Töhuku Imp Univ, 4th series, vol. 2, No. 4, 1927) on the normal growth of Paramæcium caudatum. He found that at a temperature of 24°-26° C, division occurs at the end of eight or nine hours and that there was no difference in the rate of division between examples in light and others in the dark. More than 600 specimens were killed at definite intervals after fission had occurred and they were drawn, their length and breadth measured, and their area determined by a planimeter. Immediately after fission, the daughter Paramecia increase markedly in length but decrease in breadth; that is, there is a change in their form. Size cannot therefore be estimated by measuring only the length, and as the volume could not be accurately ascertained, the most satisfactory method appeared to be the careful determination of the area. When the areas of specimens killed at known times after fission are plotted, they show that the growth of Paramecium is represented by a linear curve.

LENS DESIGN -In Scientific Paper of the Bureau of Standards, No. 550, Mr. I. C. Gardnei deals with the application of the third order algebraic aberration equations for a thin lens to the design of lenses to fulfil given conditions. Up to the present, there has been no book giving the third order aberrations in a form quite satisfactory for this purpose, and it has been difficult for a designer to get any information between that given in elementary text-books and that to be found in works on instrument design and other specialised problems. The notation adopted is substantially that of von Rohr, but by the intro-duction of a modification in that of Taylor, it has been possible to give the results in each of the two notations. The sign of the distance of a point from the lens is positive if in moving with the incident light one passes through the lens before reaching the point Designs of thin lenses and of systems contaming thin lenses and prisms are worked out in detail by the author, and the paper of 130 pages should be of great help to the optical designer.

Molecular Volumes at Absolute Zero.—In two interesting papers in the August number of the Journal of the Chemical Society, S. Sugden has shown that the simple equation  $D-d=D_o(1-T_r)^{3/10}$  applies with great accuracy to Young's results for the liquid and vapour densities of thirty substances.  $D_r$ , d are the densities of liquid and saturated vapour,  $D_o$  is the density at the absolute zero,  $T_r$  is the reduced temperature. The equation contains two constants,  $D_o$  and the critical temperature, only. It is therefore possible to calculate  $M'D_o$ , the molecular volume at the absolute zero. This magnitude,  $V_o$ , is shown empirically to be a nearly constant fraction, the values ranging from 0.264 to 0.280, for a number of substances. The value for hydrogen in 0.373. The equation proposed by Sugden is a special case of a general one proposed by Verschaffelt, but the constants chosen give better results. The results apply also to associated liquids. It is further shown that values of  $V_o$  can be predicted by adding together certain characteristic constants for the atoms and structures present in the molecule for a very large number of compounds.

RETURN CIRCUITS IN ELECTRIC TRAMWAYS.—In electric tramway systems, for the sake of economy, it is customary to use the rails as part of the circuit connecting the dynamos at the tramway power station with the motors on the car. These rails are connected through the tram wheels with the negative

poles of the dynamos, and as they have to large current, an appreciable difference of pc exists between various points on their lengths they are not insulated, only part of the return curred flows by the rails, the rest flowing through the earth. the pipes of water and gas companies, and the coverings of telephone cables. The possibilities of serious electrolytic corrosion in large telephone cables by these leakage or 'vagabond' currents has made traction engineers consider whether the present precautions are sufficient In World Power for September, G. W Stubbings gives a helpful contribution to the subject. The Ministry of Transport has imposed the regulation that the difference of potential between any two points on the rails must not exceed 7 volts. This regulation has been in use for many years and so tai has been found quite satisfactory. The replacement of overhead telephone wires by underground cables is a new fact that has to be considered. When the current flows from the cable sheath to the rails there are risks of serious erosion occurring. A further restriction has been imposed, that the maximum potential difference between the rails and a buried pipe in its vicinity shall not exceed 1 5 volts when the rail is negative to the pipe and 45 volts when the rail is positive to the pipe. This restriction seems desirable, but to apply it equitably in practice is difficult. In Great Britain, traction engineers as a rule rely on maintaining the potentials of the rails low by means of special dynamos taking current from definite points of the rails through insulated circuits Mr Stubbings considers the relative merits of this method and that of using special copper conductors. Many interesting mathematical problems arise

ELECTRIC MOMENTS OF ORGANIC MOLECULES IN Benzene Solution.—Measurements of the dielectric constants of binary systems in which the first component (eg. benzene) is known to have no electric moment allow of the calculation of the electric moment of the molecule of the second component. The equation used is a combination of the familiar Clausius-Mosotti law with a result deduced by Debye, in which the molar polarisation is shown to be a linear function of the reciprocal of the absolute temperature. In the July number of the Journal of the American Chemical Society, J. W. Williams and I J. Krchma apply this formula to the results found with a number of solutions in benzene. The values for the electric moments of the solute molecules vary from zero for carbon tetrachloride to  $1.70 \times 10^{-18}$  for phenol; ethyl ether has the value 122 10-18, chloroform 1  $10 \times 10^{-18}$ , and chlorobenzene  $1.55 \times 10^{-18}$ . These are in good agreement with previous results with the pure substances. These results are clearly of importance in certain fields of speculation in organic chemistry. An interesting result is that the moment of symmetrical xylene is very small, whilst it is appreciable in the case of unsymmetrical xylene.

The Supposed Phosphorus Suboxide,  $P_2O$ .— From time to time various lower oxides of phosphorus have been described, but most of these have been shown to be impure amorphous phosphorus. One of them, Besson's oxide,  $P_2O$ , has been investigated by Chalk and Partington, whose results are described in the August number of the Journal of the Chemical Society. It is shown that the supposed oxide is again an impure form of amorphous phosphorous, contaminated with the materials used in the preparation described by Besson. The existence of an oxide of phosphorus below  $P_4O_6$  should therefore still be regarded as extremely doubtful.

# The International Union of Geodesy and Geophysics.

HE third conference of the International Union of Geodesy and Geophysics was held at Prague on Sept. 3-10. at the invitation of the Czechoslovakian Government, though most of the sections found it necessary to hold some of their meetings in the preceding week in order to get through their programmes of work. Previous meetings held at Rome in 1922, and at Madrid in 1924, had proved to be of great value in providing an opportunity for workers in a group of sciences where international co-operation is essential to discuss methods and to arrange schemes for future work.

On the present occasion, 29 out of the 32 countries belonging to the Union were represented by delegates, who numbered more than 160. The Union, with its sections for geodesy, seismology, meteorology, terrestrial magnetism and electricity, oceanography, volcanology, and hydrology, covers a very wide field, and these triennial meetings afford an occasion when questions involving two or more of these fields of work can be discussed by those who are actually

occupied with them.

In the Section of Geodesy the determinations of gravity at sea, made by Dr. Vening Meinesz of Holland on board a submarine during a voyage to Port Said, and also during one to Java by way of the Panama Canal, were described by him, and aroused much interest. The great ocean areas were shown to be generally in a state of approximate isostatic equilibrium, except in places where crustal movement is in progress, such as the Straits of Sunda, where considerable anomalies were shown to exist. The conference expressed the hope that other nations having submarines of a suitable type will co-operate in this work of gravity determination over ocean areas now that a satisfactory method of doing so has been developed, and proved to be efficient. Dr. Vening Memesz also described certain improvements in his pendulum apparatus which he had introduced as the result of his experiences on submarine cruises. Detailed accounts of this work will be published by the Dutch Geodetic Commission.

The geodetic work which has been carried out recently on a co-operative plan by the countries on the shores of the Baltic furnished an example of an excellent piece of work, well designed and carefully carried out. It was suggested that such work might be done usefully in other restricted areas by similar co-operation. Summaries of geodetic work carried out since the last conference were communicated by many countries, and were thus made available to other geodesists much sooner than would otherwise

have been the case.

In seismology much useful work was done in the discussion of the analysis of seismograms, the improvement of telegraphic codes, the preparation of tables for use in the reduction of seismological data, etc. The conference urged that the countries concerned should improve the network of existing stations by establishing additional ones in North Spain, in the Balearic Islands, and in New Caledonia or Tahiti. A proposal of the National Committee for the United States that countries should co-operate in the study of ocean deeps was strongly supported.

The Section of Meteorology was occupied with a large number of scientific questions, among which the preparation of daily synoptic charts of the South Pacific Ocean, the extended study of solar radiation, and upper air observations in tropical regions and in the southern hemisphere, may be mentioned. The conference adopted a recommendation of the Section expressing the hope that this investigation of the

upper air in low and southern latitudes might be actively prosecuted. Now that the International Meteorological Committee finds itself very fully occupied with matters relating to the working of the meteorological services of the various countries, this Section of the Geodetic and Geophysical Union finds full employment in the discussion of many scientific matters which would probably not be dealt with by the Committee; thus, each of the two organisations work without duplicating the work of the other, but on the contrary supplementing it.

on the contrary supplementing it.

The Section of Terrestrial Magnetism had a full programme of work which included the discussion of recent work, the comparison of instruments, the design of improved apparatus, and the reduction of observations. Atmospheric ionisation and the observation of aurora also came under consideration, as well as the need for additional earth-current in-

stallations

The Section of Oceanography did much of its work by sub-committees appointed to consider the investigation of the different great sea areas, and of

tidal phenomena.

In volcanology full accounts were communicated of the recent outburst of Vesuvius, and also of the somewhat earlier volcanic activity at the island of Santorin. Certain problems connected with the transmission of waves in the earth's crust were discussed in a joint meeting with the Section of Seismology, and the thermal gradient in the crust came up for detailed consideration. The conference adopted a resolution by the Section that countries in which active volcanoes occur should be invited to undertake the measurement of the thermal gradient in various localities.

In hydrology much work was done on problems relating to the flow of water, and the transport of silt in suspension also came under discussion. By an arrangement with the International Committee on Glaciers, which was established in 1894, its work will now be transferred to and carried on by a committee of the Section of Hydrology, of which committee M. Hamberg will be the chairman and M. Mercanton the

secretary.

M. Lallemand was re-elected president of the Union up to the end of 1931, when the statutes may be revised and re-approved by the countries of the Union. He will thus have been president throughout the whole of the first period of the Union's activity, twelve years. Some changes were made in the officers of the sections, Dr. L. A. Bauer replacing Dr. C. Chree as president of the Section of Terrestrial Magnetism, and being in turn replaced as secretary by M. Ch. Maurain. M. Wehrlé becomes secretary of the Section of Meteorology.

logy.

The various communications which were made to the sections at their meetings will be published by them in the immediate future, in continuation of the publication series which each section has already

ınıtıated

The most generous hospitality was shown to the delegates both by the Czechoslovakian Government and by the municipality of the city of Prague. In addition, the members of the organising committee made excellent arrangements, by which the delegates were shown all the scientific institutions of importance as well as the numerous museums, galleries, and houses of historical and artistic interest in and near the city.

The President of the Republic was to have received the delegates on one evening, but unfortunately his health did not allow him to return to Prague to do so; the Minister of Foreign Affairs held the reception on his behalf.

On the conclusion of the conference delegates had the choice of visiting the Tatra Mountains in southeastern Czechoslovakia, or the principal health resorts, including Joachimstal, Keilberg, Karlsbad, and Marienbad.

For the next meeting the conference received in-

vitations to meet at Stockholm and at Lisbon; both were accepted in principle, but it was left to the executive committee to decide later which of the two should be definitely accepted, since the wish had been expressed by the United States Research Council that the Union's meeting should take place near in time and place to that of the International Astronomical Union, whenever this should be practicable.

# International Congress of Genetics.

THE fifth International Congress of Genetics, held m Berlin on Sept 11-18, was a very important and successful meeting. The opening addresses of welcome were given in the auditorium of the Berlin Medical Society in Luisenstrasse, while all the other sessions were held at the University (Unter den Linden) Members of the Congress were welcomed by Prof. E. Baur, chairman of the committee of arrangements, as well as by the German Minister of the Interior, the Prussian Minister of Agriculture, the head of the Berlin Medical Service, and Prof. Kniep, representing the University of Berlin. At this meeting an address was given by Prof. R. von Wettstein on the problem of evolution. Prof. S. Navashin, the distinguished cytologist of Moscow, was elected president of the Congress, a fact which is significant of the fundamental part which cytology has played in the modern development of genetics. The membership of the Congress numbered more than Mornings were devoted to general addresses, while in the afternoon the Congress met in six sections and about 135 papers were read.

The sections devoted to general genetics, cytology, and cultivated plants were particularly strong. The largest number of papers were devoted to wheat, maize, Drosophila and Enothera, as many as ten investigators of Enothera being present. A number of papers were concerned with the subject of mutation; several were concerned with the statistics of inheritance, and several with crossing-over. A double attack on the theory of crossing-over led to an extensive and lively discussion in which the great strength of the theory was brought out. In this connexion an important paper by Prof. F. Bernstein pointed out new mathematical relationships which follow from the mechanical theory of crossing-over.

The address of Prof. H. J. Muller, of Texas, on the production of mutations in Drosophila by treatment with X-rays, was generally regarded as the most important contribution to the Congress. Mutations were produced in large numbers by subjecting males or females to X-rays for different periods. Four periods were used, and with the longest period of treatment the rate of mutation was 150 times that in the controls. Genes were affected equally throughout the chromatin and an increase in the X-ray dosage was found to increase the rate of 'point' mutations. Sperm used in fertilisation 6 days or 12 days after treatment showed no difference in the rate of mutation-production. The presence of large numbers of mutations was also found to have little or no effect on sperm viability.

In the X-chromosome of Drosophila, mutations normally appear at the rate of not more than I in 1000. In these experiments many more mutations appeared in the X-chromosome than have occurred in it naturally in all previous experiments. Such well-known mutations as rudimentary wing, broad wing, cross-veinless, white eye, and vermilion eye appeared repeatedly, but there was an enormous increase in the number of lethal factors. It was also found that the effect of X-rays on the ovaries per-

sisted after treatment, a fact which has an important bearing on some of the present methods of X-ray therapy. X-rays also increased the number of c-factors, which reduce the frequency of crossing-over. Rearrangements of loci were also found to occur in the chromosomes. From various experiments the conclusion is reached that the gene is probably compound in the chromosome, composed of 2 or 4 parts, in preparation for later cell divisions. The great majority of the mutations produced are lethal or otherwise invisible, their presence being proved by later breeding experiments

In the genetic work on Enothera, the greatest interest centred around the linkages between chromosomes, which were demonstrated by Cleland and Gates. Each species and mutation is found to have a fixed arrangement of its chromosomes during diakinesis and on the heterotypic spindle. In some wild species all the chromosomes are linked into a ring of 14, while in others there are 7 free pairs. Still other species, such as E. lamarckiana and E. ammophila, have 1 free pair and a ring of 12. In the mutations from E. lamarckiana the arrangement is also a definite one, E. rubrinerus and E. rubricalyx, for example, having 4 free pairs with a ring of 6 chromosomes, while E. deserens has 7 free pairs.

This constitutes essentially a new type of nuclear differentiation. It appears that it will also be of fundamental importance as furnishing the basis for the unique phenomena of linkage of characters into complexes in Enothera, which has not hitherto received an explanation. It is already indicated that where a large amount of chromosome linkage occurs there will be only two (twin) or three hybrid types, while in crosses between forms with many free pairs of chromosomes much segregation will occur. Shull described a new gene mutation from E. lamarckiana, a simple Mendelian recessive showing linkage of the ordinary type.

Among the studies of cereals, Dr. C. L. Huskins showed the existence of speltoid and dwarf wheats having respectively 41, 42, 43, and 44 chromosomes, parallel to the fatuoid series which he has recently discovered in oats. He also described a fatuoid chimæra in oats, and this appears to complete the parallelism in the behaviour of fatuoid oats and speltoid wheat.

Dr. M. Navashn made an important demonstration of the nuclear differences in species and hybrids of Creps. Some of the species differ in the presence of a satellite or a terminal 'head' to the chromosome, and in the hybrids it is shown that the former may be transformed into the latter. This is the first time that a definite change in the structure of a chromosome as the result of hybridisation has been shown. The study of this type of chromosome differentiation is in its infancy and will lead to large results.

Among general addresses to the Congress may be mentioned that of Prof. O. Rosenberg, of Stockholm, on species-formation with multiplication of chromosomes, and Prof. H. Federley, of Helsingfors, on the

chromosome relationships in hybrids. Owing to illness, Prof. C. Correns was unable to give his address on non-Mendelian inheritance, but addresses were given by Dr. Vavilov on the geographical gene-centres of cultivated plants, and by Dr. Blakeslee on the genetics of Datura. Dr. Crew, of Edinburgh, discussed the organisation and function of an animalbreeding research station.

Miss Pellew and Miss de Winton discussed recent work with the garden pea and with Primula sinensis Many other subjects of special interest came before the Congress. Practically every phase of genetical fact and theory was represented, from the study of variegation, clones, and inbreeding to species-crosses, the geographical distribution of genes, and such evolutionary topics as convergence, the unpacking theory of Bateson, and a statistical study of fossil

Ammonites.

In the section on human genetics there were several papers on twins and on the blood groups. Prof. van Bemmelen described the inheritance of curly hair as an apparently simple dominant through several generations. Other papers considered the inheritance of shortsightedness, musical ability, general ability, sex, and psychological peculiarities as well as interracial inheritance in man. In the smaller section of eugenics a number of less strictly genetical questions were discussed.

The excursions formed an important part of the meeting. A ladies committee arranged numerous excursions to places of interest, and a visit to Wannsee and Potsdam was largely attended. But most valuable was the visit to Prof. Baur's Institut fur Vererbungswissenschaft, where his extensive experiments with Antirrhinum were demonstrated, and to the laboratories of Profs Correns, Goldschmidt, Hartmann, Nachtsheim, and others at the Kaiser Wilhelm Institute in Dahlem There were also excursions to Petkus and Ruhlsdorf to study pigbreeding

A reception and dinner was given in the Rathaus by the Municipal Government of Beilin, and the Congress closed with a dinner in the Zoologischer Garten on Sept. 17. This was followed, however, by short visits to horticultural institutions and a four-day excursion to Quedlinburg, Halle, Weimar, and other places, where various plant and animal-

breeding establishments were inspected.

The Proceedings of the Congress are to be published promptly and will constitute a valuable survey of the present problems in genetics. The next Congress is to be held in America in 1932—under the presidency of Prof T. H. Morgan. The present Congress, which was the first since the 1911 meeting in Paris, has served to show the fundamental part which cytology has played in the development of genetics during the last fifteen years. It is safe to say that no complicated genetic problem can now be solved without the aid of cytological research, and nearly all the most important recent developments of the subject have had a cytological basis. This mutual support of cytology and genetics is one of the most promising features for the future of genetics.

R. Ruggles Gates.

# Conference on Adult Education.

CENTURY ago the Mechanics' Institutes were developing among artisans a new enthusiasm for study of the sciences instrumental in bringing about the industrial revolution. One of the marked defects in adult education nowadays is the neglect of science, though here and there a class in biology or some related subject may be found. It is the more cheering, therefore, to learn that the British Institute of Adult Education not only devoted its recent Conference, held at Balliol College, Oxford, on Sept. 23-26, to discussion of this situation, but also can report a singularly interesting and useful series of meetings. The Institute had previously sent to each of those present a copy of the latest report produced by the Adult Education Committee of the Board of Education— "Natural Science in Adult Education" (H M. Stationery Office. 6d net) The main points which emerged from the speeches and discussions were that the study of science should be an integral part of adult education: that students will be forthcoming if the subject is taught in a humanistic spirit; that fuller co-operation between universities, technical colleges. local education authorities, and voluntary organisations is essential; and above all, that the supply of teachers capable of treating science in a broad as well as a thorough fashion must be greatly increased.

Commenting on the Board of Education report, Sir Benjamin Gott maintained that a real interest in natural science exists among ordinary people and can easily be developed if the prospective student is made aware that he will be studying something about his home, his health, his work—and if teachers will simplify their language. But boys and girls must be caught when they leave school, and not allowed to drift till they reach the twenties. Moreover, it must be recognised that over-specialisation in teaching is an evil: teachers are needed who can show the interrelation of sciences. Mr. Norman Walker stressed the importance of the experimental method-of which he gave a fascinating example—and its power to win the lasting devotion of very humble and unlearned people, though perhaps he exaggerated his advocacy when he remarked that "those who have no capacity for teaching should leave the profession -or lecture ' "

In a brilliant address, Prof. Desch showed how even technological studies could be treated humanistically. by presenting them in a historical and biographical setting and explaining their sociological significance. He suggested that the bridge between science and other liberal studies might be found in sociology, and declared that our need is not met by the addition of scientific and humanistic studies one to the other, but only by a synthesis of the two groups Dr. Varley said that, for purposes of administration, education is cut up into too many divisions, and pointed to the importance of the fact that technical colleges are now recognised as centres of higher education without limitation of the curriculum. Classes in literary subjects are provided there and attended by many students for purely cultural purposes. The trouble is that young folk who finish their technical courses at the age of nincteen or twenty have been absorbed for some years in vocational preparation, have not developed an interest in humanistic studies, and see nothing further for them m our educational system. He therefore advocated the bringing of adult classes into the technical college and the provision there of a Common Room so that a social atmosphere might be created. Prof. Nunn, in the closing session of the Conference, urged that the science to be taught to adults must be the real thing, not merely the history of science (valuable as that aspect is), and that the natural result would be to make people scientifically minded. He observed a rhythmic process in which from wonder students pass to a sense of the practical value of science and then to a desire for systematised

thought In his view the study of science would lead to a deeper and more widespread interest in philosophy. Sir John Sankey, in his presidential address, spoke of the way in which science, having made increased productivity possible, should also show the way to a proper distribution of our material resources and to the enrichment of our social and spiritual life. Above all, it should teach us a respect for fact and a humility in judgment which would transform our personal and social relationships.

# University and Educational Intelligence.

BIRMINGHAM —The new biology block of the Unversity, which is to be formally opened by the Prime Minister on Oct. 20, is a very important addition to the building on the Edgbaston site. The new block forms part of the 'curtain' fronting on University Road, and extends from the chemistry block to the Harding Library, a distance of nearly 100 yards. It provides accommodation for the Departments of Botany, Zoology, and Biochemistry and Brewing

The ground floor is allotted to zoology, and comprises large and well-lighted elementary, advanced, honours and research laboratories, museum, insect room, departmental library, rooms for the professor and staff. lecture room, dark room, stores and animal A large part of the first floor is occupied by the Biochemistry and Brewing Department, and contains a large general laboratory, analytical and research laboratories, professor's and lecturers' rooms and laboratories, an admirable microscope room, balance room, incubator room, lecture room, and a departmental library The remainder of this floor is assigned to botany, and includes a large and welllighted herbarium, staff rooms, and special rooms for The second floor constitutes the main part of the Botanical Department, with large elementary and advanced laboratories, a laboratory for vegetable physiology, museum, lecture room, and departmental library, professor's and lecturers' rooms and laboratories, balance room, dark room, and store-

Rising above the general roof level of the 'curtain' is a large theatre which will be shared by all these departments. The building is heated throughout with hot water circulated by electric pump from a steam heated calorifier. General ventilation is furnished by fans in addition to the usual window openings. The windows on the south side look on to the great court, and those on the north look across the University Road to the land (at present arable and pasture) which has been recently acquired as an extension of the University site.

Important additions have also been made to the Chancellor's Hall (the hall of residence for men students). This will now accommodate about 100 men, and the new wings are to be opened by Mr. Baldwin.

London.—The following courses of free public lectures are announced: Six on "Vision." by R. J. Lythgoe, at University College, at 5 o'clock, on Oct. 10, 12, 17, 19, 24, and 26; three on "Hydrogen Ion Concentration," by Mrs. P M T. Kernidge, at University College, at 5 o'clock, on Oct. 14, 21, and 28; and four on "Heat Transfer in Reciprocating Engines, including Internal Combustion Engines," by Prof. A. Nagel of Dresden (in English), at the Institution of Civil Engineers, at 5.30 o'clock, on Oct. 11, 14, 18, and 21. The "Stevenson" free public lecture on "Eugenics in the Future" will be given by Major Leonard Darwin at Bedford College for Women on Oct. 25 at 5 15.

Newcastle-on-Tyne —Mi J O Cooper has been appointed lecturer in zoology at Armstrong College in succession to Dr A. D. Peacock, who is going to University College, Dundee, as professor of zoology.

The Huxley lecture in connexion with the Charing Cross Hospital Medical School will be delivered at the school on Thurslay, Nov. 24. by Sn Archibald Garrod, who will take as his subject "Diathesis"

SIR ARTHUR KEITH IS giving museum demonstrations at the Royal College of Surgeons, Lincoln's Inn Fields, on Oct 14. 21. and 28, at 5 P.M., on recent researches into the reproduction and growth of bone, rheumatic and other changes in joints (Strangeways Collection), and congenital dislocation of the hip and other joints. The lectures are open to advanced students and medical practitioners.

"Professional Schools, Post-Graduation Courses, Specialist Studies in the Universities and University Colleges of Great Britain and Ireland, Session 1927-28." That is the title of a pamphlet recently issued by the Universities Bureau of the British Empire. "Of their [the universities] special fields of study." says the prefatory note, "the greater part is common ground, yet each of them has its special plots which it cultivates, in some cases with a view to the needs of the province which it serves, in others because it has been agreed, or arranged, that it shall undertake work for which there is but little demand." The purpose of the pamphlet is therefore to indicate the respects in which the institutions undertake work which is not common to them all Particularly useful is the section describing the distribution of subjects of study. They are arranged in alphabetical order under the usual headings of arts, science, law, medicine, and technology, and ought to save considerable research in the individual university calendars. Thus, in the case of protozoology, London (Lister Institute), Edinburgh, and Glasgow are indicated; in the case of railway economics, the reader is referred to London and Manchester In technological subjects such as photography, rubber, sugar, textiles, etc., the special provision made by certain technical institutions is described.

The East London College Calendar for 1927-28 announces the opening of a new hall of residence for men students, the requisite funds for which were provided by the Drapers' Company (£6000) and H.M Government (£5000). The College Council has instituted a fund for the encouragement of original investigations by the staff and students and offers three research studentships of £50 annually. It is one of the few university institutions in Great Britain which offer courses in aero-engineering. The Northampton Polytechnic Institute also has an aeronautical laboratory, and its Engineering Day College announcements for 1927-28 give particulars of third and fourth year courses in aeronautics, aero-engines, and aeronautical drawing and design. Another speciality of this Institute is its department of applied optics, in which work is conducted as part of a complete scheme of optical education in London, including advanced classes for graduates at the Imperial College of Science and Technology. The Battersea Polytechnic, which offers full day and evening classes in preparation for University of London degrees in science, engineering, and music, includes among the subjects of its specialist courses architecture, flour-milling, domestic science teaching, and health visiting. A special feature of its organisation for social life is its day students' representative council, which tends to the maintenance of some continuity in the activities of the various students' clubs and societies.

# Calendar of Discovery and Invention.

October 2, 1901—The first British submarme, launched at Barrow on Oct. 2, 1901, was 63 ft. long and 11 ft. 9 m. wide. From the sixteenth century onwards, numerous attempts were made to produce a boat to travel under water, but the early models failed because they relied on man-power for propulsion. The greatest impetus to submarme building came with the 'Holland' vessel, constructed about 1897 by J. P. Holland in America. It was propelled by a gasolene engine on the surface, and used electricity for under-water work. It also had planes, which could be inclined to assist in diving and rising

October 3, 1846.—Gun-cotton was the invention of Prof Schonbem, of Basel, and was made known in 1846. On Oct 3 of that year, the Diet of Frankfurt voted a recompense of 100,000 florins to Schonbem and Dr Boettger, as inventors of the explosive, provided the authorities of Mayence, after seeing it tried, pronounced it superior to gunpowder as an explosive. Improvements were made by Baron von Lenk, an Austrian officer, about 1852, and in 1862 details of the manufacture were communicated to the British Government.

October 4, 1877.—The Ingram web rotary machine, invented by Mr. (later Sir) W. J. Ingram, M.P., for printing illustrated newspapers, was first used to print the *Illustrated London News*, Oct. 4, 1877.

October 5, 1896.—At the Paris Academy of Sciences on this date, MM. Berthelot and Vieille read a paper describing researches which had been made with the view of seeing what precautions, if any, are necessary in the preparation, compression, and storage of acetylene for commercial purposes. Acetylene was discovered by Edmund Davy in 1836, and first systematically examined by Berthelot. Wohler, in 1862, prepared it by the action of water on calcium carbide, but its use as an illuminant only became practicable in 1892 when Moissan and Willson showed that it was possible to make calcium carbide on the commercial scale in the electric furnace. Storage of the gas by dissolving it in liquids such as acetone was first suggested by Claude and Hess in 1896. Later Janet and Fouche found that acetylene dissolved in acetone absorbed by a suitable porous material could not be made to explode.

October 6, 1807.—Potassium was isolated by Davy by electrolysis of the fused hydroxide on Oct. 6, 1807 By a similar method Davy isolated metallic sodium. The method of manufacture on the commercial scale was given its first impulse by Deville in 1854, and in consequence of the improved processes it became possible to sell sodium at 10s. a pound in 1868. The modern Castner electrolytic process was introduced in 1890.

October 7, 1847.—Sir Isaac Holden and Samuel Cunliffe Lister were responsible for great developments in the machinery for wool-combing. On Oct. 7, 1847, a patent was taken out in their joint names for a new method of carding and combing and preparing genappe yarns, and when the machinery had been brought as near perfection as possible, factories were built which in time became the largest wool-combing concerns in the world. The business was concentrated chiefly at Bradford, to which city it brought prosperity.

October 8, 1884.—On this date, Rodney, an ironclad battleship of the Benbow class, was launched at Chatham. The modern ship of the same name was laid down on Dec. 28, 1922, with her sister ship Nelson Her length is 702 ft, beam 106 ft., mean draught 30 ft., and normal displacement 35,000 tons.

T

### Societies and Academies.

Paris.

Academy of Sciences, Sept. 5 -Paul Marchal The natural strains of Trichogamma -Riquier · The investigation of the numerical solutions of any system of integral algebraical equations with any number of unknowns - Léon Pomey · The existence of non-linear, partial differential equations which are quasi-normal.—J A Lappo-Danilevski The algorithmic solution of the problem of Riemann.—Jean Chazy. The advances and retardations of the times of passage of Mercury on the sun's disc—Raoul Ferrier The theory of the molecular field—F. Gonseth and G. Juvet The equations of electromagnetism and Schrodinger's equation in a five dimensional universe —Lucien Vallery The stability of the catalytic properties of palladiumised asbestos. Details of experiments bearing on the determination of hydrogen in the atmosphere by the action of asbestos coated with palladium. Traces of hydrogen arsenide and antimonide do not appear to poison the catalyst, neither does the catalytic power of the metal appear to be affected by repeated use —Pierre Thomas and Mile Marie Sibi Contribution to the study of the structure of jellies Researches on the crystallisation of l-arabinosazone By the addition of a suitable foreign substance it is possible to modify the crystallisation of arabinosazone in such a manner that a pseudo-gel is produced. It is probable that the presence of impurities is a necessary condition for the production of gels of this nature, containing long hair-like crystals.—A Demolon and G. Barbier The application of viscosimetry to the study of colloidal clay. Some information can be obtained of the modifications of the state in a suspension of colloidal clay, especially the influence of electrolytes, by measurements of viscosity It should be noted, however, that these suspensions do not obey Poiscuille's law, and hence the results have only a relative value -Pereira de Sousa: The basalts of Portugal. At Lisbon and in its neighbourhood there have been at least two series of volcanic eruptions showing differences in their chemical composition -O Munerati and A. Milan: The possibility of detecting the presence of forage beet-root and semi-sugar beet-root amongst sugar beet at the commencement of growth.-L. G. Seurat: The presence of Mercierclla enigmatica m a river m Tunis—G. Mouriquand, A. Leulier, and P. Sédallian: The pH and the alkaline reserve in C-avitaminosis —Edouard Chatton: The meiotic gametogenesis of Paradinium Poucheti.

# CAPE TOWN.

Royal Society of South Africa, July 20.—A Ogg: The symmetry and crystalline structure of the crystals potassium, ammonium, rubidium, and casium sulphate. The crystals were shown to belong to the space group  $Q_h16$  in Hilton's notation ( $V_h$  16 Schonflies notation). The elements of symmetry are

Reflection planes  $(100)_{\frac{1}{4}}$ ,  $(100)_{\frac{3}{4}}$ . Glide planes  $(010)_{\frac{1}{4}}$ ,  $(010)_{\frac{3}{4}}$ . Translation c/2,

 $(001)_{\frac{1}{4}}, (001)_{\frac{3}{4}}.$  Translation  $\frac{a+b}{2}$ .

with the corresponding dyad screw axes and centres of symmetry. The unit contains 4 molecules and the molecule has a molecular plane of symmetry. The proposed structure shows the  $\mathrm{SO}_4$  group in tetrahedral form, the distance between S and O centres being  $1.5\,\mathrm{\mathring{A}.U.}$  The nearest approach of a K centre to an O centre is  $2.7\,\mathrm{\mathring{A}.U.}$ , and slightly increased distances for other members of the series. The structure gives an explanation of the twinning of these crystals and the

formation of almost true hexagonal prisms -P. R v Copeman. Studies in the growth of grapes (Part 3). The effect of environment upon the growth constants. The same type of equation is applicable to grapes grown in various localities, but the values of the constants in the different equations are directly affected by changes in environment. It seems that plants are affected by environment to a greater extent than animals. Changes due to environmental conditions are greater than those due to seasonal conditions—J. F. V. Phillips The behaviour of Acacia Melanoxylon R Br. (Tasmanian blackwood) in the Knysna forests an ecological study 'Blackwood' acts detrimentally upon the regeneration of the more important forest species, and is a plant which might become commoner it forests containing its dormant seeds were to be distributed. Despite its value as a tunber tree and its efficiency as a killer of weeds on open sites, it is not considered wise to plant the species in gaps in the main forests.

#### WASHINGTON.

National Academy of Sciences (Proc., Vol. 13, No. 7, July).—George A. Baitsell Additional evidence as to the intercellular formation of connective tissue Inoculation of living tubercle bacilli into the testis of the guinea-pig causes degeneration of the seminiferous tubules. In the intertubular spaces an abundant exudate appears which is quickly transformed directly into fibrous tissue.—W. M Copen-Results of heteroplastic transplantations of the heart rudiment in Amblystoma embryos. The whole and also part of the heart rudiment was transplanted from a large species of salamander into a smaller species and vice versa. The development of the whole heart rudiment and also the pulse rate seemed to depend mainly on its origin. The nerve supply comes from the host species but the heart muscle retains its own specific rhythm—A. E. Hopkins: Vision and retinal structure in mice. By means of an electrical punishment plate, mice in a box were trained to choose one of two outlets with coloured papers or illuminated with coloured lights. The animals seem generally to be colour-blind; their retine contain no structurally differentiated cones—J. B. Green and R. A. Loring: Zeeman effect and structure in the spark spectra of tin (preliminary report) —Francis A. Jenkins: The structure of certain bands in the visible spectrum of boron monoxide.-Carl Barus: Pressure phenomena of the mucronate anode Measurements with the interferometer Ugauge indicate that sharp surfaces of maximum and minimum potential surround an anode and cathode respectively at a distance of about half a millimetre from the electrodes—J. W Beams and Ernest O. Lawrence: On the lag of the Kerr effect. Light from a spark gap passes through a Nicol prism, two Kerr cells and another Nicol. The plates of the Kerr cells are connected with the spark gap by variable leads; if he leads are equal and there is no lag or equal lao in both Keir cells, no light passes out of the system. With different liquids in the Kerr cells, or with the cells at different temperatures, the difference of the lengths of the leads divided by the velocity of light gives the relative time lag of the Kerr effect The lag increases with viscosity and decreases with rising temperature, is constant for a given liquid for all wave-lengths, and is greater for polar molecules. The results accord with the theory that the Kerr effect is due to orientation of molecules with lag due to molecular, frictional, and inertial forces.—L. B. Loeb and L. Du Sault: Mobilities of ions in acetylene hydrogen mixtures. The mobilities of positive and negative ions in acetylene are probably the same; a lingher mobility observed for the negative ion is due

to the presence of electrons. In mixtures with hydrogen, there is no certain indication of clustering effects—Francis B Silsbee Current distribution in supraconductors The critical current' is that at which the magnetic field due to the current itself is equal to the critical magnetic field.—F. Zwicky: On the reflexion of electrons from crystal lattices The whole effect is produced by a few lattice planes near the surface A theoretical explanation is developed—R. C Gibbs and H. E. White. Displacement of certain multiplets and multiple levels for elements in the first long period Using the irregular doublet law and the regular displacement law of multiplets, certain characteristic multiplets of Cr III and Mn III have been located -R. A. Millikan and I. S Bowen Energy relationships and ionisation potentials of atoms of the first row of the periodic table in all stages of ionisation The most useful graphical exposition is to plot atomic number against the square root of the frequencies of the energy levels.—F E Wright: Polarisation of light reflected from rough surfaces with special reference to light reflected by the moon Measurements have been made with a polarisation photometer filled to the 12-in refractor of the US Naval Observatory of the amount of polarisation of light reflected by the moon At new moon and full moon, practically none of the reflected light is polarised, the maximum amount occurs at the ends of the first and third quarters and does not exceed 15-25 Comparison with the effects given by per cent. terrestrial substances indicates that the surface of the moon turned towards us consists largely of pumiceous substances high in silica, powders of transparent substances, quartz porphyries and possibly trachytes and gramites. There seem to be no dark rocks low in silica such as basalts, no masses of iron, no large nce masses or glassy obsidians, and no powders of basic rocks.—Willard J Fisher, Esther L Wurl, and Marjorie S. Desmond: The trails of two periodically flickering meteors.—Bernard Lewis: The unimolecular decomposition of azo-methane; the adequacy of activation by collision.—G. L. Clark, R. H. Aborn, E. W. Brugmann, and R. L. Davidson: On X-ray diffraction patterns from liquids and colloidal gels (see NATURE, July 23. p. 119)—Florence R Sabine and Charles A. Doan The effect of tubercle bacılli and the chemical fractions obtained from analysis on the cells of the connective tissues in rabbits. The action in labbits of the proteid and phosphatid fractions from human tubercle bacilli was followed by neutral red. The proteid is toxic, is associated with damage to endothelium and has a pressor effect on clasmatocytes; the phosphatid causes local production of tubercular tissue.—D H. Campbell. The embryology of Equisetum debile Roxb. The buds producing secondary shoots are endogenous, thus resembling the primitive fern. Ophioglossum.—F E Denny. The effect of small amounts of chemicals in increasing the life activities of plants. Citrus fruits which are commercially ripe are often partly green. If they are stored in a chamber containing a small concentration of ethylene (1 in 5000), they ripen off quickly. The metabolism of the fruit is hastened. Similar enhanced activity has been found in dormant buds and other plant tissues stimulated by various apparently unrelated chemicals. The effect may be of the nature of an incipient wound response—Neil M. Judd: The architectural evolution of Pueblo Bonito. Pueblo Bonito sheltered two distinct peoples; the founders, who used a single type of masonry, and a second group, who evolved three types of masonry and created for Pueblo Bomto its prestige The site was abandoned about a thousand years ago. Neither people had beasts of burden or metal tools.

# The Interpretation of Science.

THE British Association is not the only organisation in Great Britain having for its avowed object the advancement of science. Every learned society, all the various bodies dealing with the professional interests of scientific and technical workers, are whole-heartedly devoted to the same cause. But the British Association has very special functions in addition to those of giving "a stronger impulse and a more systematic direction to scientific inquiry" and promoting "the intercourse of those who cultivate science." It was also called into being to obtain more general attention for the objects of science, for which purpose it set itself the task of familiarising the general public with the progress of scientific research and developing a consciousness of the effects of such research upon man's material and intellectual progress. Such activities are essentially complementary to those of the learned societies, the function of which it is to provide specialists with the necessary facilities for meeting others engaged in the same particular branch of science, and for the appraisement and publication of their work.

Specialisation in science is inevitable. It is indeed doubtful whether the present division of the scientific members of the British Association into sections and sub-sections corresponding with the principal branches of science is adequate to their needs. Thus, the exponents of a growing and most important branch of science like bio-chemistry may find the time quite insufficient which is allotted to them in the chemistry section, or in joint meetings of that with other sections Again, those engaged in aeronautical research may feel that neither the Section of Mathematical and Physical Sciences nor that of Engineering gives their field of inquiry the consideration it deserves. It would occasion no surprise, therefore, if further subdivisions were made in the near future.

It is perfectly clear that the more specialisation there is in science the more need there is for the Council of the Association to exercise the greatest care and vigilance to prevent the obscuration of its main object. Even for scientific workers there are special advantages attached to membership of the Association. At each yearly meeting they are provided with unrivalled opportunities for meeting with others drawn from all parts of the world and discussing their work, for surveying the progress made in their respective branches of science and for becoming acquainted with the advances made in practically every other field of scientific endeavour.

In return for these very real privileges gained for them by the growing prestige of the Association, they could and should be expected to pay more regard to the desire of the lay members who attend its meetings, and the general public which reads the reports, for the presentation of the advancement of science in language intelligible to the non-specialist

It must be remembered that the British Association is not purely a professional body like the British Medical Association, Iron and Steel Institute, Institution of Naval Architects, and similar organisations which hold meetings at different centres year by year It invites the general public to become members, and many of them do so at every place where a meeting is held Association were a closed corporation of workers in pure and applied science which met to discuss the position and progress of particular branches of natural knowledge, the character of the proceedings would be its own affair As, however, a fairly large proportion of its annual members belong to the lay public, it owes a debt to them as well as to the scientific members; and we doubt whether this duty is fully met by the provision of the Citizens' Lectures, though the lecture on "Energy" delivered by Sir Oliver Lodge at Leeds was a brilliant example of what can be accomplished in this direction. We suggest that each section might appropriately devote at least one afternoon meeting to a lecture or discussion of what may be conveniently described as a Royal Institution type, that is, intended for intelligent people who are interested in advances of science and yet are not actual workers in the particular department to which the subject refers. It would be found that there are many scientific workers who would be glad to attend such accounts of progress in fields outside their own, in addition to members of the general public who join the Association in the hope of obtaining such enlightenment.

As to the presidential addresses, however specialised may be the field of research of any president of a section, upon him or her rests the responsibility not only of relating special studies with one particular branch of science, but also of making every effort to establish contacts with other fields of scientific inquiry and to demonstrate the essential unity of purpose of them all. This responsibility can be shouldered neither by the General Committee nor by the Council. But the Council of the Association obviously has the right to expect that organising committees will assist in preventing the annual meeting from developing into summer vacation meetings of a number of learned societies.

If any one doubts that there is a growing tendency in this direction, let him examine the subjects chosen by authors and the summaries supplied for inclusion in the journal of transactions of the Association for the past few years. Some of the subjects are so specialised in scope that it is improbable they could have been of interest to more than a few members of the particular section to which they were delivered. Many of the summaries are couched in such highly technical language that even the special scientific correspondents of the great newspapers find them unintelligible.

There would be little occasion for lengthy comment were it only the youthful aspirants for scientific honours against whom this charge of obscurity could be brought We could rely upon time to purge them of the conceit of demonstrating familiarity with their newly acquired forms of expression in order to win a reputation for erudition Unfortunately, some of the addresses delivered by sectional presidents at Leeds displayed the same weakness. From the point of view of title, subject matter, and form of presentation, they were alike calculated to produce in many members of the Association a feeling of bewilderment. We do not doubt that these addresses are noteworthy contributions to the problems of particular fields of work, but as they are printed we suggest that they need not be read in the section rooms, or at any rate only those parts which can be followed intelligently by the section as a whole. There may still be some members of the general community whose respect for science is in inverse proportion to their capacity for understanding what is presented to them, but they are a dying race. Thanks to the reforms brought about in our national system of education since the beginning of the century, there is a large and everincreasing army of people equipped with enough knowledge of science to be hungry for more. The publication and large sales of certain popular handbooks on scientific subjects is a clear indication of this interest in the activities of our research workers.

The members of the general public who attended the Leeds meeting are in a position to judge of the quality of the communications presented as addresses and papers. Those who perforce had to rely on newspaper accounts of the proceedings will be mystified by the paucity of the references to those subjects which they regard as the exclusive domain of the scientific worker. While this can partly be attributed to the contempt which some reporters and editors have for the level of intelligence of their readers, most of the fault lies

with the authors of papers They are prone to ignore the fact that with so wide a range of choice of subject matter for copy, the press representatives will invariably seize upon that which is presented with such clarity as to dispense with the need for interpretation. For this reason the sections dealing with education, agriculture, and economics receive more than their proportionate share of attention in the newspapers.

It may be urged that certain subjects cannot be resented in a form calculated to appeal to a wide p 'alic. If that be the case, they should either not fina Nace in the proceedings of the British Association, or alternatively, the papers given at the annual meeting should be divided into two categories, those which are intended to appeal to a wide public and those which are for the exclusive benefit of specialists. It is inconceivable that in any of the branches of science represented by the thirteen sections there should not be sufficient material each year upon which to base an address to nonspecialists, and presidents of sections, as well as other authors of papers, would be well advised to prepare summaries of the main features of their addresses for advance distribution to the press They can rest assured that unless they can first interest the newspaper reporters they will have little opportunity of interesting the public in their work. They need not fear, moreover, that a reporter will rest content with a summary. A test of good journalism is the originality with which a subject is treated. Given a summary as a setting, the reporter will find jewels with which to adorn it

The advancement of science depends upon the encouragement of research. The public must be better informed if it is to appreciate to the full the need for more and more research. It will not willingly endow what it cannot understand scientific workers who attend the yearly meetings of the Association ask themselves why, in its wisdom, the Council holds each meeting in a different centre of population in the country Presumably it is done for its propaganda effect Bringing scientific workers into personal relationship with various sections of the community helps to destroy the illusion that we are a race apart. Clear exposition of science should also dispel the idea that scientific experiment is mere legerdemain, its mysticism heightened by a rigmarole of complex terminology. Explicit statement is the necessary precursor of wide publicity, without which there cannot be general appreciation of the aims and methods of science, of what science has achieved and what it might achieve for the human race.

# Science in Literature.

The Short Stories of H. G. Wells Pp. 1148 (London Ernest Benn, Ltd., 1927) 78 6d. net.

OTHING is so significant of the power of the old classical tradition as the extent to which the literature of fiction remains comparatively unmoved under the shock of scientific discovery. For the intellectual revolutions which have been effected during this past century by a mere handful of blandly inquiring scientists can be matched only by the social and industrial transformations to which they have unconsciously contributed in no small measure

To a scientist a new field of human experience and expression is opened up. He sees life unfolding, not merely as the old interplay of human emotion and passion, but rather in response to the widening environment developed by man's increasing knowledge. In the field of science, for him who has eyes to see, dramatic material is not far to seek, but current fiction remains singularly aloof. Here and there a detective, a pathologist, or a medical practitioner is created who plays his part against a suggestive background of mysterious knowledge, but there is no novelist, with the exception of Mr. H. G. Wells, in whom the dramatic element in scientific discovery evokes a sufficient response to urge him to action.

The strong human impulses associated with love and sex which have formed the keynote of so much of modern fiction are not absent in the work of Wells—far from it—but the psychological behaviour of the scientist, his interests, his urges, the material he handles, and the stage he treads, constitute a region into which none other than Wells has dared to enter

Coming to literary work from the field of technical knowledge, Wells has made the amazing discovery that a scientific training, far from being a handicap, is a positive blessing. A good novelist, if he is anything, is pre-eminently a psychologist. It is his function, by means of the technique of storytelling, to observe, to describe, and to analyse the thoughts and actions of mankind, and not merely that aspect of mankind constant throughout time, but mankind in the making. He stands at the point of vantage who absorbs with understanding the newer knowledge. Being artistic, such an analysis—in the creation of a novel it is really a synthesis—is not scientifically systematic differs from a study of a scientific problem in this respect, that no two novelists in their treatment will produce the same result. The final product is

dependent on the mentality of the solver the psychological study developed by the novelist is, as often as not, a reflected study of the author Wells stands at this point of vantage, and in describing his vision opens up his mind.

Here, then, in the present group of short stories, we see Wells, a young imaginative artist, striding boldly into the field and with a few strokes creating a world which hums strangely in the ears of the old classical school. Tuned to the mentality of the scientist and alive to the trend of scientific thought, Wells enters the arena of fiction armed with weapons denied to his professional colleagues He may manœuvre in regions of the arena with assurance where others must hesitate to tread, and the earlier stories in this extraordinary collection show Wells disporting himself gaily and masterfully among the fantastic notions born of much of the speculative science of the late Victorian era.

Early hesitant knowledge of time and space are handled with assurance and imagination in "The Time Machine," "The Plattner Story," "The Strange Case of Davidson's Eyes." Sometimes his boldness is preposterous, as when in "My First Aeroplane" he makes a machine in 1912 stand up to treatment that no self-respecting aeroplane in 1927 would possibly tolerate without destruction. At other times it is almost prophetic, as in "The Land Ironclads," where in 1903 trench warfare and tanks are described in unerring detail Again and again he traces the emergence of a world of wheels, and shafts, and furnaces.

It is easy to say that, in those early days of Wells's literary work, the young man is merely tickling the palate of the reader with a series of extravagant ideas. While it is probably true that a number of these stories are scarcely more than this, there recurs continually the suggestion that if mankind would only realise it, the potentialities for good and evil in modern scientific discovery on the mechanical side are enormous. There is, for example, "A Dream of Armageddon," "A Story of the Days to Come," and so on. There appears the implication to the scientific man that he must give himself pause to consider whither his newer knowledge may drive mankind, and to the layman the startling question as to whether he is indeed ready to receive this strange knowledge.

The theme changes slightly as Wells borrows from his biological experience. The power of natural selection as a factor in evolution is violently forced to our notice here and there. In "The Country of the Blind," the capacity of the human organism to adapt itself to environment, and the extent to No. 3023, Vol. 120]

which refinement in the senses may proceed in response to needs, are brought out with the skill of a master "The Empire of the Ants" teaches how survival of the fittest is by no means identical with survival of the most desirable In "The Time Machine "we are projected forward into futurity and are horrified to discover that mankind has long passed the zenith of its highest development and a kind of retrogression or involution has set in, 'n place of the higher evolution.

These ideas may be fantastic, they may be mere examples of mental agility and imaginative strokes of a young man in a field yet unopened to assured knowledge. But we begin to perceive that in the background of Wells's mind there exists a dominating urge. Mankind itself raises a problem of colossal magnitude—how to utilise the accumulating wealth of scientific knowledge in the design of a super-race—of a civilisation devoid of the stupidities and absurdities of social life as we know it.

These stories where they touch this issue scarcely do more than raise it Some indication of Wells's own line of approach to this difficult issue is provided by glimmerings of Utopias of various kinds that sparkle out here and there. It is in his larger and more mature works that these ideas are worked out in greater detail, but, on the whole, Wells on the constructive side is much less satisfying than at his favourite game of thought provoking. Utopias are literally as old as Adam, but it is permissible to doubt whether the mental exercise in their design ranks higher than that used in the solution of a crossword puzzle.

It is possible that in a sense they may serve the useful function of preparing the minds of some for the possibilities that might be achieved, for the ideals to which to strive. But imaginative gropings in a dim future, with roseate pictures of the dawn of a new era when man will grasp the forces of Nature in the hollow of his hand, will not provide a solution of the immediately pressing problems of production, distribution, and exchange; for the question uppermost in every one's mind, both scientist and layman, is, "What to do now?"

The kind of promise the imaginative Wells has held out in these early stories is not fulfilled by him in his later work. Doubtless, had his numerous love novels been left unwritten, the world of literature would have been enormously the poorer, but the far-reaching and vital questions which Wells himself raised have really not been faced by him. Instead, he has left it to the politicians, content to be a mere finger-post pointing towards an inaccessible region of the horizon. H. LEVY.

### The Formation of Roads.

- (1) The Science of Roadmaking · a Scientific and Practical Treatise dealing with Road Construction in its Modern Forms, for the Use of Surveyors, Contractors, Asphalt Plant Managers, etc. By John Wilfrid Green and Charles Norman Ridley Pp. xv + 138 + 5 plates. (London Crosby Lockwood and Son, 1927) 10s. 6d net
- (2) Management and Methods in Concrete Highway Construction By G L Harrison Pp ix +242 (New York McGraw-Hill Book Co, Inc., London McGraw-Hill Publishing Co, Ltd., 1927) 15s. net

IT will be generally recognised that the formation and laying-out of highways and crossroads have, until recent years, been far more in the nature of a science than an art, though art has begun to enter into its kingdom since the passing of John Burns's Town Planning Act, the first of the kind in the British Isles Not that with the advent of art into the matter of road-making science will function to any less degree. For though it is not every one who holds the view that science must of necessity retrograde in the absence of advancing, yet it is certain that modern progress in regard to the modes of travel must carry in its train scientific progress.

When any one takes thought of road-making, the memory of what the Romans accomplished in this direction is mevitably to the fore. Without staying to consider such local routes as they constructed in the City of the Seven Hills and other places of importance, it will suffice to recall those great military highways which so aided them in the control of their vast empire. England still possesses portions of these notable enterprises—as witness Watling and Stane Streets and others—which radiated from London (the Augusta of Roman days) throwing out their tentacles in various directions.

These Roman roads were, however, undoubtedly purely military and scientific; military in their nature and purpose, and scientific in their construction: art could claim no part in them. In the magnificence of Roman conception a military road was driven from centre to circumference with as close an approximation to a radial line as could be achieved; natural obstacles were for the most part overcome by means of bridges and tunnels, according to the gradients encountered. Mansiones or camps were established en route, though it is the customary Latin word for 'camp' which has survived to this day in the nomenclature of so many of our towns

The Roman roads were made to endure, like the Egyptian monuments of earlier date. It is only as the nature of the passing traffic alters and its volume increases almost beyond conception, that other routes, other methods and other construction, have had to supersede a system of incomparable virtue.

Perhaps it is giving too great credit to the British character to attribute the passing of the Roman highway to the necessities of the twentieth century—for the truth is, that long before its advent, British insouciance had consigned the memory of these military trophies to the limbo of neglect, if not, indeed, of oblivion.

The Roman thoroughfares were constructed on good scientific principles, a firm bottoming was obtained by ramming small stones and bats of brick into the ground, and on this foundation was laid a pavement of large stones accurately fitted like a mosaic pattern, the interstices being carefully jointed in cement. Where large stones were unobtainable, then a species of concrete was substituted, composed of small hard stones bound together with lime

Of course, these main highways accounted only for a mere fractional part of the means of transit necessary throughout Great Britain. Here British sluggishness of temperament asserted itself unalloyed. A mere path, sufficiently wide to enable a pack-horse to bear its burden, would gradually form itself, rather than be formed, in the required direction; even then it would not go straightforward, but would meander between and around the trees, thus in time providing us with those serpentine courses, which have a charm to the eye, even though regarded as practically undesirable. These tracks invariably followed the line of least resistance; the fordable part of a stream would be approached, whatever deviations might thereby be rendered necessary.

Thus these initially unobtrusive paths gradually became beaten tracks, widening sufficiently in time to admit of the passage of carriages meeting en route, though frequently even this was not accomplished. But as for any scientific construction, it can but be said that science was conspicuous by its absence. If Irish main roads were passably good (for the period), English were passably bad, whilst Scotch (according to a countryman's evidence, namely, Macadam) were atrociously bad

In England the main idea, so late as the early years of the nuneteenth century, seemed to be to barrel the roadway by arching it almost inconceivably high at the crown, with a very steep gradient to either flank. When the mevitable occurred, and the road became rutted as in a night-mare, the curative process consisted in filling up the ruts and making the crown usable by means of vegetable débris, loose stones, and general rubbish, all brought to a sufficiently smooth condition, so as to receive the cachet of the local authority (such as it was), and then—all would be da capo

This period of darkness endured until about a century ago, at which time the enlightened labours of Telford, Macadam and others served to bring about such improvements as paved the way for modern scientific production. There are many who still regard the method developed by Macadam as of value, even under the changed conditions of the traffic problem—mechanical transport, heavy in its nature and dense in its massing, convulsive in its movements and rapid in its passage. But science, ever on the alert, introduces new solutions to meet altered conditions, and so we find macadamised roads giving place to the use of granite setts, concrete, wood blocks, rubber surfacing, asphalt paving, and, most interesting perhaps of all, the reinforced concrete treatment of the substructure.

The progress of science makes welcome the production of literature dealing with the subject of road-making, and the two books under notice would seem to be one the corollary of the other, or perhaps they should be regarded as mutually interdependent. Messrs. Green and Ridley consider the subject from its scientific basis, dealing successively with hydrocarbons, bitumens, asphalt, sand, tar and pitch, cement and concrete chapter dealing with molecular structure and valency is peculiarly interesting, perhaps more so than many that follow. The authors have a high opinion of asphalt for the surfacing, and certainly it seems to take rank after macadam from the viewpoint of anti-slipperiness. The authors do well to state that "the reliance too often placed on maintenance guarantees by road surveyors is causing the substitution of a cheaper material, to the possible detriment of asphalt paving in general." Regarding the suitable-mixture diagram shown on page 49, there seems to be a lack of agreement with the text on the previous page; for the diagram apparently indicates the medium group as giving 12-50 per cent., and the fine group, 30-60 per cent., whereas the text reverses these figures.

It is properly remarked, that "in taking a No. 3023, Vol. 120]

sample of sand for the mechanical analyses or grade composition, care should be taken to secure same from the inside of the heap "; and the recommendation of tar macadam surface for motor traffic is well advised. But why should such solicitude be expressed on page 71 for fish, respecting the use of tar 2

The practical consideration of construction is developed in Mr. Harrison's book in a very interesting and masterly manner, and the business aspect is thoroughly regarded. Indeed, the main adverse criticism to be offered arises from the madequacy of many of the half-tone illustrations, which often need the base reference to produce intelligibility. It is a fact also, that some people might think that there is too great a fetish made of timekeeping to a second, but this meticulousness is recommended in the interests of the contractor. It is not possible to agree with the author (see page 184) that the table in fig. 7 shows a large percentage of time lost due to water trouble, though such loss is made manifest in the next figure The series of sixteen chapters is well worked out, and the graphs and diagrams in general are clear. It is not to be disputed that (within certain limits) the greater the method which can be introduced into a contract the more it makes for final satisfaction. This was eloquently manifested recently in the erection in Piccadilly of the new Devonshire House, which was worked out upon a schedule prepared by its American architect on lines of exactitude, such as Mr. Harrison recommends in his book on concrete highway construction. PERCY L. MARKS.

## Brain and Mind.

- (1) Thought and the Brain By Prof. Henri Piéron. Translated by C. K. Ogden. (International Library of Psychology, Philosophy, and Scientific Method.) Pp. xvi + 262. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., Inc., 1927.) 12s. 6d. net.
- (2) The Mind and its Mechanism: with Special Reference to Ideo-Motor Action, Hypnosis, Habit and Instruct, and the Lamarckian Theory of Evolution. By Paul Bousfield and W. R. Bousfield. Pp. vii + 224. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1927.) 9s. net.
- (1) THE last thirty years have witnessed the inauguration of a new era in the study of mental phenomena, the introduction of the discipline of scientific induction into a field of inquiry in which the deductive procedures of the

scholastic method had run riot for many centuries. The study of the evolution of the nervous system and the experimental investigation of its mode of working prepared the way for the understanding of the biological processes that express themselves as mental phenomena. Such researches as are associated with the names of Sherrington and Pavlov are clearly of fundamental importance for the interpretation of the working of the mind and for correcting the assumptions of introspective psychology. Armed with the results and the methods of experimental physiology, the psychologist has devised tests of his own to apply the method of experiment to the phenomena of mind and, under the leadership of Spearman, has attempted to express in mathematical form the fundamental analysis of mental ability so that it can be measured and subjected to the test of experiment.

Perhaps the most fruitful field of psychological inquiry has been provided, however, by the clinical study of the mental effects produced by injuries to the nervous system—in particular the vast experiments provided by bullet wounds in the War. Moreover, the anxiety states created by the abnormal stress and strain of trench warfare, and the moral and intellectual damage resulting from encephalitis lethargica since the War, have shed important light upon the emotional side of the mind's working. It is no exaggeration to claim that these three departments of clinical study have provided a new revelation of the dependence of mental and emotional expressions upon neural mechanisms. In the technical medical journals a vast amount has been written upon these subjects: in his great monographs on sensation and aphasia, Head has given his interpretation of the mental significance of nervous phenomena: many other books have been published dealing with the expression of the emotions and the psychological significance of the activities of the bram: but it remained for some psychologist to expound in generally comprehensible terms the new light shed upon the workings of the mind by recent research in clinical medicine

This difficult task has been attempted by Prof Henri Piéron, of the Collège de France. He has subjected to a critical but sympathetic examination the medical reports on the results of injury to brain and nerves, and has succeeded in giving a fair and reasoned analysis of the results achieved It is particularly interesting to find a French author expounding so lucidly Head's researches on sensation and aphasia. Though his acceptance of Head's

views is qualified, he has given his readers an unbiassed account of the methods and results and a generous appreciation of their significance to psychologists. His discussion of aphasia is particularly instructive. Summing up the history of research into the significance of speech-defects resulting from injuries to the brain, he gives a clear and just estimate of the contributions of Gall, Broca, Bastian, Charcot, Wernicke, and Pierre Marie; he concludes: "At present, in an atmosphere of thought impregnated with Bergson's powerful critique, so quickly assimilated that it has become impersonal, it is the intellectual analysis of the function of language, such as that attempted by Head, which has come to the front, and we are returning to the profound views of Hughlings Jackson, which were obscured by the brilliance and prestige of Charcot." This frank admission is distinctive of the fairness and impartiality of the author.

In translating this book into idiomatic English. Mr. Ogden has successfully accomplished a task of no mean difficulty. But it is unfortunate that he did not submit the proofs to an anatomist. for several of the technical terms, though literally translated, have emerged in curious forms. Thus the intracortical fibres known as the stria of Gennari, often referred to by French anatomists as the band of Vicq-d'Azyr, are called in this book (p. 254) "the bundle of Vicq-d'Azyr," which is the name of a very different kind of structure in another part of the brain. The figures also contain many inaccuracies-in particular Fig. 2 on p. 6. Special mention is made of these defects, because this book is one that will be particularly useful to the medical student; and some teachers might hesitate to recommend a work containing such lapses. In a new edition it would be wise to provide an entirely new set of illustrations. For the book deserves better treatment in this respect.

(2) The book by P. and W. R. Bousfield is a speculation that attempts to give concreteness to McDougall's conception of a psychical structure as part of the mechanism of mind. Thus the authors claim that they "have endeavoured to expand this more or less metaphorical conception by the hypothesis of a real psychic structure which is an essential part of the organism."

This search for an elusive mind-stuff seems to have been prompted chiefly by McDougall's claims that "the progress of our knowledge of the brain has shown conclusively that there exists no one part in which all sensory paths converge and which might be regarded as a sensorium commune" (p. 17),

and further, "that there exists in the brain no such physical medium of composition, and that the processes of the several sensory nerves simultaneously excited do not affect any common material medium to produce in it a complex physical resultant" (p. 18).

More than a quarter of a century ago I invented the term 'neopallium' for the definite cortical area where all sensory paths do converge and pour their currents into a continuous sheet of grey matter, which is a most definite and indubitable 'physical medium of composition.' Hence I am unable to accept the basal assumption of this book.

G. ELLIOT SMITH.

# Oxford Histology.

Histological Technique. for Normal Tissues, Morbid Changes and the Identification of Parasites By H. M. Carleton. Chapters vii. and viii, in collaboration with Frederic Haynes. (Oxford Medical Publications.) Pp. xv + 398. (London Oxford University Press, 1926.) 16s. net.

THIS book has been written by a young Oxford histologist who was trained in the Department of Zoology and Comparative Anatomy of Oxford. The author has had special experience in medical parasitology and a training in the various recently developed techniques for the study of the cytoplasmic inclusions of the cell. The present volume is not intended to be an exhaustive work on microtomy for the research worker in the same way as "The Microtomist's Vade-Mecum," but is planned to act as an introduction to the subject, and to lead up to more advanced investigations.

The first book on modern histological methods which emanated from Oxford was that of Gustav Mann, entitled "Physiological Histology," 1902 When the reviewer was histologist at Oxford, there was a faded piece of paper pinned behind the histology sanctum sanctorum which set forth the sales of Mann's book. So far as the paper showed, the book was a failure—that is, commercially—but "Physiological Histology" even now contains material not found in any other text-book of microtomy, and was a decade or so before its time.

Another noted Oxford histologist, Dr. S G. Scott, was a splendid type of the medically trained scientist. Scott specialised in the precise application and standardisation of the better-known laboratory techniques, such as those of hæmatology and colour reactions. Much of this worker's success was due to his special know-

ledge of the dyeing industry of Leeds Scott died during the War, and his book was never written Both "The Microtomist's Vade-Mecum" and "Histological Technique," however, contain many of Scott's formulæ and 'tips'

In recent years, owing not only to the kindly interest which Sir Charles Sherrington has shown in this subject, but also to Dr Carleton's enthusiasm, the Oxford Histology Department has been enlarged, and its facilities have been brought upto-date, "Histological Technique" will show that nowhere else is histology better taught and histological methods better understood

Much of Dr Carleton's book will be familiar to users of the "Vade-Mecum," and "Mallory and Wright." but it is not to be imagined that the author has not cut new ground The exposition of the carefully weeded out material is clear and concise, and undoubtedly the most admirable part of the volume, from the student's point of view, is the arrangement of "Tables of Faults" Why do sections curl? Why does the tissue fall out of the block? Why does the ribbon refuse to form? and so on In three columns, we have "Fault," "Diagnosis," "Remedy," as for example, "Sections crumble," "Paraffin too soft," and "Cool the block," as the remedy. Thus, a person working alone will find every facility for tracing out his difficulties and eliminating them. Some of the statements regarding the difficult chemical side of the subject found in Chaps, vii and viii, which were written in collaboration with Frederic Haynes. are a little doubtful, and one feels that this is the least happy part of the book

We are convinced that "Histological Technique" fills a long-felt want, and that the book is certain to go into many future editions. The author is to be congratulated.

J. BRONTE GATENBY.

# Citrus Fruits.

The Cultivation of Cutrus Frunts. By H. Harold Hume (The Rural Science Series) Pp. xxi + 561. (New York: The Macmillan Co., 1926.) 21s net.

crops cannot be over-estimated, for it includes fruits of such general use as the orange, lemon, lime, and grape-fruit, with others of less economic importance. This being the case, comprehensive books upon the subject are necessary from time to time, in order that growers in the many countries where these fruits are cultivated may be kept informed of improved varieties and better methods of cultivation and marketing as they are evolved.

All these points and others are dealt with in the work under notice; in fact the scope of the book is scarcely described by the title, for although a good many pages deal with the cultivation of Citrus fruits in a concise and altogether excellent manner, historical, botanical, and marketing problems are dealt with quite as succinctly.

Although the author only sets out to describe the position that Citrus fruits hold in the United States of America, he gives a fund of information that will be found to be of value to growers in other parts of the world. Commencing with a chapter on the "Commercial Importance of Citrus Fruits," the author indicates by tables the growth of the industry in Florida and California from the years 1886-87 to 1923-24 inclusive His records are taken from the number of boxes of fruit handled by the railway companies during that period, and it is illuminating to learn that whereas in 1886-87 1,260,000 boxes were despatched from Florida and 840,560 from California, in 1923-24 Florida sent away 20,399,614 boxes and California 24,292,800 boxes. In the chapter dealing with the botany of the Citrus fruits, the author gives descriptions not only of the species bearing marketable fruit but also of allied species and the few interesting hybrids that have been raised. He takes a limited view of both genera and species. The trifoliateleaved section, for example, that is so well represented by Citrus trifoliata Linn., he places under the generic name of Poncirus, whereas the Kumquat group appears under Fortunella. limits the range of the species retained in Citrus. Thus the lemon appears as C. medica Linn, the lime as C. aurantifolia Swingle, the shaddock as C. maxima Merrill, the pomelo or grapefruit as C. paradisi Macf., the sour or Seville orange as C. Aurantium Linn., and the sweet orange as C. sinensis Osbeck. The cultivated groups of Citrus truits are then divided up and the varieties cultivated in America are dealt with. Some 49 varieties of sweet orange are described under the sub-heads Spanish oranges, Mediterranean oranges, blood oranges, naval oranges. Sixteen varieties of pomelo or grape-fruit are described, with numerous limes and lemons.

The cultural part of the book deals with all operations from propagation and planting to the care of the mature trees. Manuring, treatment of diseases, pruning, collecting the crop, and many other aspects are discussed. Handling the crop and marketing is also a very useful section. The author is to be congratulated upon the production of a very complete and useful book. W. D.

# The Calculus of Variations.

Calculus of Variations By Dr A. R Forsyth.

Pp xxii + 656 (Cambridge . At the University Press, 1927) 50s. net.

PROF. FORSYTH'S latest work appears opportunely at a time when there is quite a notable revival of interest in the calculus of variations. To those who desire an account of the subject which, while modern, sound, and practical, is free from the extreme rigour so popular in certain quarters, this volume will be most welcome.

The first chapter contains a discussion of the early investigations associated with the names of Euler, Legendre, and Jacobi. Here the discarding of the irritating &-notation originally introduced by Lagrange has greatly clarified the exposition. In the second chapter an account is given of Weierstrass's modifications of the analysis when both the independent and the dependent variable are subjected to variations. The four following chapters deal with extensions to the cases in which the integrals involve derivatives of higher order than the first and more than one dependent variable.

Up to this point the variations considered are of such a nature that one smooth 'characteristic' curve is deformed into a neighbouring smooth curve. Such variations are described as 'weak' variations. In order to obtain complete solutions of the problems of the calculus of variations, it is necessary to consider the possibility of small 'jagged' or 'strong' variations. The discussion of such variations has shown that, while the tests employed in the older analysis are necessary, they are by no means sufficient; and, indeed, it has been found that some of the most important results believed to have been established by the older methods are no longer valid. Weierstrass investigated one simple type of these 'strong' variations, and an account of his work, and of his E-function, is given in chapter vii.

The eighth chapter deals with relative maxima and minima of single integrals, and the remaining four chapters contain extensions to double and triple integrals, the analysis in these naturally becoming more complicated. Throughout the book there are numerous examples fully worked out.

Though the calculus of variations has been studied spasmodically for some two hundred years, its development has scarcely yet reached a stage at which it would be possible to write a compact account of the subject suitable for use as a college text-book; but, to original workers, this treatise should prove both useful and stimulating.

#### Spectra of High-frequency Discharges in Super-vacuum Tubes.

The experiments of Kirchner (Ann. d. Phy., 4, 77; 1925) and of Gill and Donaldson (Phil. Mag. 2, 129) have shown that a tube, pumped down to what is usually termed a non-conducting vacuum, will give a brilliant discharge if excited at comparatively low voltage at a frequency corresponding to a six- or seven-metre wave, the current being fed to the tube through external electrodes of tin-foil. During the past summer we have made a further study of the phenomena exhibited by these high-vacuum tubes, with especial reference to the spectra of the discharge

The tubes were first given a drastic cleaning with caustic potash, alcohol, chromic acid, and distilled water. They were then dried and exhausted with a Holweck molecular pump, the walls being heated repeatedly during the process. A tube provided with internal electrodes, in the pump circuit, showed no discharge when connected to an induction coil giving a two-inch spark. We then excited the tube provided with electrodes of tin-foil with an oscillating circuit giving a three-metre wave. A brilliant blue discharge at once appeared (hydrogen spectrum), the general appearance of which would have led one to believe that the pressure must be of the order of a millimetre.

Discharges under the above conditions are attributed, by their discoverers, to a to-and-fro oscillation of the electrons, the time of transit down the tube being less than the time of the half oscillation of the electrical circuit.

We found that, if the pump was kept in action while the tube was excited, the blue hydrogen spectrum gradually disappeared, being replaced by the olive-green discharge characteristic of pure oxygen, while the tube walls phosphoresced with a very brilliant ruby-red light. A photograph of the spectrum showed the line and band spectra of oxygen, together with many carbon lines, the pair of double lines in the region \$2850 being especially prominent. On continuing the pumping and excitation for an hour the oxygen spectrum faded away, followed by the carbon lines, until only the double pair remained, at least with moderate exposures. The red phosphorescence was present with tubes of soft glass, pyrex glass, and fused quartz.

A similar red phosphorescence has been noticed by one of us during an investigation of the hydrogen spectrum, with a very long tube, brought to the 'white-stage' (that is, with the walls thoroughly dehydrated by long operation with a heavy current and continuous pumping). On exhausting to a high vacuum and admitting a little oxygen, the walls phosphoresced with a pink colour under the influence of the discharge.

Later in the summer, one of us made some further experiments with one of these tubes in collaboration with Prof. T. R. Merton at his private laboratory. The tube had been sealed from the pump in Tuxedo, and as a result of continued operation showed the red phosphorescence but feebly when excited by an oscillation of a seven-metre wave-length. On substituting an oscillator giving a thirty-metre wave we obtained a fairly strong red glow on the walls. Using

one electrode only, we found that a magnet, brought close to the walls, caused a concentration of the red glow on the near side of the tube, the deflexion of whatever caused the phosphorescence of the glass indicating negative electrons moving away from the electrode At the other end of the tube, the magnet repelled whatever caused the glow to the further wall of the tube, indicating electrons moving towards the electrode.

We believe that phosphorescence is associated in some way with the presence of positive ions of oxygen, but the exact mechanism of its production has not been ascertained. An investigation of the inner wall of the tube by polarised light, to detect possible changes in the surface layer of the glass, will be made in the near future, for it seems probable that the oxygen is derived from the silicon oxide. The carbon undoubtedly is due to vapour from stop-cock grease R W Wood A L. Loomis

The Alfred Loomis Laboratory, Tuxedo Park, NY.

#### The Fields of Force in the Atmosphere of the Sun.

On me signale une note de G Hale, insérée avec le même titre dans votre journal le 14 Mai dernier. La note est consacrée aux petites lignes noires, plus ou moins courbes, qui apparaissent tout autour des taches dans les images monochromatiques de la couche supérieure de l'hydrogène, et auxquelles Hale a donné le nom caractéristique de "Solar Vortices." On distingue le cas de la tache simple isolée et le cas de deux taches voisines ayant des polarités opposées, et formant un groupe bipolaire. Dans ce dernier cas, les lignes noires autour des deux taches rappellent parfois les lignes de force d'un barreau aimanté.

Or mon nom est cité comme attaché à une explication spéciale du solar vortex; mais l'explication qui m'est attribuée est mexacte ou insuffisante. Je suis conduit à préciser certains détails et à donner mon opinion actuelle sur tous les points soulevés par Hale et Buss dans votre journal les 14 et 28 Mai 1927.

I. Mes premières idées sur la question ont été résumées dans les Comptes rendus de l'Académie des Sciences, Paris, le 10 Janvier 1910, les 29 Mai et 6 Juin 1911. Le solar vortex n'est pas la cause du champ magnétique de la tache; il peut être simplement un effet du champ magnétique général du Soleil sur les files de gaz ionisé qui, dans les couches supérieures, se rapprochent de la tache (Evershed). On pout invoguer aussi la rotation de l'astre et le principe d'inertie. Le champ magnétique général, peut-être un peu modifié par le voisinage de la tache, est analogue au champ terrestre; sa direction est plus ou moins vers le nord et assez éloignée de la verticale. Dans ces conditions, il courbe dans le même sens les files gazeuses de deux quadrants opposés; 1 mais, dans les deux autres quadrants, il a surtout pour effet d'élever les gaz ou de les abaisser. Or ces différences se retrouvent dans la plupart des images de l'hydrogène photographiées à Meudon. D'ailleurs il faut considérer non seulement les actions aérodynamiques et électromagnétiques, mais les actions électrostatiques, qui peuvent donner un champ identique à celui d'un barreau aimanté.

Finalement, dans mon esprit, le solar vortex était un phénomène secondaire; l'attraction de la couche supérieure par la tache et la répulsion de la couche renversante avaient pour moi une importance plus grande, la cause de cette attraction et de cette

<sup>&</sup>quot;On peut objecter que la raie  $H\alpha$  de l'hydrogène est émise par l'atome neutre, mais, aux températures élevées de l'astre, l'atome passe souvent de l'état neutre à l'état ionisé, et inversement.

répulsion étant d'ailleurs mal connue, comme aussi la cause du fort champ magnétique de la tache, qui reste le fait le plus curieux et le plus énigmatique.

II. Dans ces dernières années, mes idées ont évolué Le rayonnement corpusculaire des couches solaires, longtemps ignoré ou méconnu, a une importance capitale; et plusieurs faits nouveaux m'obligent à admettre que la partie la plus intense de ce rayonnement est émise par des corps radioactifs. Dans les couches solaires successives, les deux rayonnements, ondulatoire et corpusculaire, se substituent l'un à l'autre incessamment; mais le rayonnement corpusculaire, beaucoup plus absorbable, est vite airêté, et la terre en reçoit seulement une petite partie, qui produit nos aurores polaires (Carl Stormer) et les orages magnétiques simultanés.

La petite aiguille aimantée apparaît ainsi extrêmement précieuse, puisqu'elle nous révèle un rayonne-ment nouveau de l'astre. A Meudon, nous enregistrons ses variations sur un papier sensible qui noircit sans développement, et l'astronome a sous les yeux les pointes de la courbe de déclinaison, au moment même où elles se produsent. De plus on prend comme horloge le Soleil qui tourne; et la pointe est représentée dans le temps par la longitude du centre du Soleil au même moment Or on constate que les pointes des orages magnétiques sont séparées, en longitude, par des intervalles qui sont des multiples de 60°, 30°, et 15°. Un certain ordre apparaît là où la confusion était d'abord la note dominante, J'ai présenté ce résultat comme un fait d'expérience dans votre journal le 30 Octobre 1926. Le Dr Chree, il est vrai, a fait quelques objections; mais j'estime qu'elles sont écartées dans les deux notes que j'ai publiées ultérieurement aux Comptes rendus le 26 Décembre 1926 et le 4 Juillet 1927.

Finalement, tout se passe comme si le rayonnement corpusculaire de nos orages émane d'une couche solaire profonde qui tourne comme un corps solide; et cette couche offre au moins 24 volcans permanents. répartis uniformément autour de l'axe de rotation, et d'activité variable, qui rejettent au dehors la matière ionisée ou radioactive des masses intérieures. Cette division régulière est celle des corps à symétrie circulaire qui se refroidissent. Cependant, les particules rejetées par les divers volcans ont à peu près les mêmes vitesses, exactement comme si elles étaient émises par les mêmes corps radioactifs. De plus les recherches poursuivies à Meudon depuis 1925 par Mlle Maracineanu ont montré que le rayonnement solaire peut modifier ou provoquer la radioactivité dans les corps (uranium, plomb, curvre); il doit avoir à un plus haut degré la même propriété dans le Soleil lui-même. Il est donc légitime d'admettre que les volcans solaires rejettent des corps radioactufs.

Le rayonnement corpusculaire de la couche profonde a été présenté par moi dès le début comme la cause première de tous les phénomènes (taches, facules, filaments, protubérances) observés sur le Soleil et ses dépendances. Si les corps radioactifs interviennent, plusieurs faits singuliers s'expliquent aisément.3 Chaque corps radioactif se décompose en donnant naissance à un autre corps, le plus souvent aussi radioactif; il est caractérisé par sa période et la nature de son rayonnement ( $\alpha$  ou  $\beta$  ou  $\beta\gamma$ ). Si la période est courte, le phénomène est vraiment explosif, et on a d'une part un orage à commencement soudain, et d'autre part les points brillants des protubérances éruptives, qui émettent des jets

lumineux dans plusieurs directions. Lorsque le volcan rejette un corps à particules s et un corps à particules a, un groupe bipolaire de deux taches se forme, les particules s'élèvent pendant que les corps radio-actifs s'abaissent. Le champ magnetique général du Soleil déplace les deux corps dans des directions opposées et les sépare; de plus les deux corps forment avec leurs particules deux courants électriques, paralleles et de sens opposé, qui donc se repoussent Plus tard, lorsque le rayonnement a diminué, les deux corps, qui ont des charges électriques opposées et croissantes, s'attirent.4 corps donne une tache lorsque l'énergie des particules émises par elle atteint un certain niveau, les deux taches pouvant naître et disparaître à des moments différents. Les particules qui s'élèvent en s'écartant repoussent les gaz de la couche renversante, et donnent naissance aux petits filaments de la pénombre, dirigés vers le centre de la tache.6 On retrouve tous les détails de l'observation.

Le champ magnétique élevé des deux taches et aussi l'opposition de leurs polarités sont plus difficiles à expliquer, comme aussi la température plus basse de la tache, au moms lorsqu'on n'a pas recours à de gros tourbillons, dont la cause première nous échappe; mais la place manque ici pour exposer tous les points de la question. Je remarquerai seulement que cette étude des orages magnétiques conduit à des idées nouvelles sur la constitution du Soleil.

III. Dans sa note, Hale expose quelques résultats obtenus avec son nouvel appareil, le spectrohélioscope, qui est difficile à réaliser, et lui fait certainement honneur L'appareil décèle, quoique d'une manière indirecte, les mouvements radiaux qui échappent au spectrohéliographe; il a été employé à la reconnaissance de petits filaments ("long dark flocculi") animés de mouvements rapides, qui abou-tissent à une tache. Hale ajoute que le spectrohélioscope est seul capable de déceler ces phénomènes solaires qui sont fugitifs.

Cette dernière assertion me paraît exagérée. Nous avons à Meudon, à côté des spectrohéliographes, des spectroenregistreurs des vitesses, qui, en service depuis 22 ans, ont décelé souvent des phénomènes analogues à ceux décrits par Hale. Je partage aussi l'opinion de A. Buss, qui annonce avoir observé souvent les mêmes faits avec le spectroscope ordinaire A ce sujet je remarque que, en 1892-1894, le simple spectrographe a reconnu les propriétés générales des vapeurs enregistrées par le spectrohéliographe, et qu'il a révélé seul leur position exacte dans le Soleil ; l'épreuve du spectrohéliographe est l'image de la chromosphère entière.

En fait, pour les phénomènes étudiés récemment par Hale, ce qui importe, ce n'est pas tant l'appareil que la continuité de l'observation. L'astronome solaire, avec les appareils simples qui sont un spectroscope à réseau et une boussole disposée comme cidessus, fera des observations très utiles, en particulier sur les phénomènes fugitifs, s'il a la patience de suivre le Soleil pendant de longues heures.

H. DESLANDRES. (Directeur des Observatoires de Paris et Meudon.)

<sup>4</sup> En général, le rayonnement corpusculaire est le plus fort au moment où le corps radioactif est rejeté par le volcan solaire. Les taches et facules, d'autre part, ont un rayonnement corpusculaire plus faible, et les points ordinaires de la surface un rayonnement encore plus faible. D'où les différents effets observés avec l'aiguille aimantée, lorsqu'un volcan et une tache traversent le méridien central de l'astre.

<sup>3</sup> D'après cette explication, les deux taches du groupe bipolaire peuvent avoir des différences dans leurs spectres, et la durée de la tache est liée à la période de ses corps radioactifs.

<sup>6</sup> La répulsion de la couche renversante implique un tourbillon cellulaire, déjà admis par moi en 1910, adopté aussi par Bjerknes en 1926; un autre tourbillon cellulaire, superposé et de rotation contraire, correspond à l'attraction des gaz de la couche supérieure.

le 25 Août.

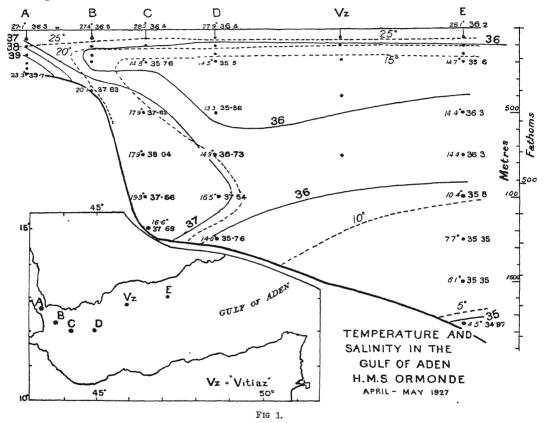

<sup>&</sup>lt;sup>3</sup> Dans sa critique, le Dr Chree considère seulement la période qui correspond à 60° de longitude; mais. dès le mois de Mai 1926, l'ai annoncé les périodes de 30° et de 15°, aussi intéressantes que celle de 60°.
<sup>3</sup> L'intervention de corps radioactifs a été admise aussi par Lenard

# Temperature and Salinity Observations in the Gulf of Aden.

Observations of the warm bottom current flowing out of the Red Sea have been made in the past by the surveying ships Pola, Vitiaz, and Stork in the Straits of Bab-el-Mandeb, and the abnormally high temperatures below the surface in the Arabian Sea have been attributed to this source. Advantage has now been taken of some tests of deep-sea thermometers made in April and May of this year in H.M.S. Ormonde (Commander C. W. Rice) under the direction of Rear-Admiral H. P. Douglas, Hydrographer of the Navy, to follow this outflow eastwards.

At all the positions A to E (Fig. 1) there was either

phosphorus in and off the Gulf of Aden was equivalent to 0.03 mgm of phosphorus pentoxide per litre in the upper 50 m., from 200 m. downwards it increased, reaching 0.143 mgm at 1750 m. Atkins and Harvey (Nature, Nov. 28, 1925) analysed samples collected by R.R. S. Discovery in the region between Portugal and the Canary Islands, and directed attention to the increase of phosphorus with increasing depth; they found none in the upper layers and about 0.075 mgm. at 2000–3000 m. The remainder of the special samples from the Gulf of Aden were mixed in two lots and examined for total arsenic by the Government Chemist. He found the equivalent of 0.005 mgm. per litre of arsenicous oxide in the depths 500–1750 m., but the upper 50 m. contained less

an increase in the temperature and salinity at a depth greater than 200 m., or at least a considerable decrease in their rate of fall; this probably marks the upper limit of the water containing an admixture from the Red Sea. The axis of the current was at a depth of from 750 m. to 1000 m. at A to D and at a slightly smaller depth at E. The temperature and salinity on the bottom at E in 1750 m. are such as might reasonably be expected at this depth in the open sea. The Valdivia in 1899, at practically the same position, found  $3\cdot7^\circ$  C. on the bottom, which is in close agreement if allowance is made for a depth greater by 90 m. The salinity determined at the same time,  $38\cdot47$ , has always seemed doubtful in combination with such a low temperature, and there can now be little doubt but that it is erroneous. The Vitiaz at Vz found a slight rise of temperature, which was probably due to the outflow, but her observations did not go deeper than 800 m.

The analysis of a few samples specially preserved with toluene show that the average content of

than 0.001 mgm. per litre. It appears, therefore, probable that arsenic is removed by plankton organisms much as phosphorus is

I have to thank the Admiralty for permission to publish these results.

Donald J. Matthews.

The Admiralty, S.W.1, Aug. 31.

#### Imperial Science Services.

In the leading article in Nature of Sept. 17 in relation to the Imperial Agricultural Conference, it is pointed out that in some branches of science there is "a lamentable deficiency" of young men coming forward to take up research. Special reference is made to research in genetics, but the statement applies to most branches of applied biology. Whilst such positions as are available in the British Isles are eagerly sought, those in tropical colonies, and to a less extent in the Dominions, are not generally attractive to university graduates in biology.

No. 3023, Vol. 1201

It appears to me that the main reasons for this state of affairs are—first, that biologists in such posts are largely isolated and lose touch with progress in their science; and, secondly, that once they have embarked on such a career they have little prospect of returning to a good position at home—This second reason is obviously partly due to the first, but it is largely also due to the fact that men in the Dominions and Colonies rarely get the chance of applying for the vacancies that occur in the British Isles. Such vacancies are usually advertised in the leading English papers and in Nature, but by the time these papers reach readers in the more distant Colonies and Dominions, the date for sending in applications has usually passed.

For example, forty-four posts of various kinds in the British Isles were advertised in Nature in July and August this year. I find that the average length of time from the first appearance of the advertisement to the latest date for receiving applications was twenty-one days. The period varied from three to fifty-nine days, but in only ten of the forty-four was it greater than four weeks. It seems obvious that most of those responsible for fixing the terms of application for scientific posts in Great Britain have

not yet learnt to think imperially.

Positions in Government departm

Positions in Government departments and official institutions in the Dominions are generally only advertised locally. For example, in two of the Australian States the position of Government Entomologist recently became vacant, and in each case was filled after advertisement only in Australian papers Probably there were numerous entomologists in India and the tropical Colonies who would have applied for these positions if they had had the opportunity

The recent Colonial Conference recommended the formation of a Colonial Agricultural Research Service directed by a Council, one of the functions of which would be "the organisation of a 'pool' of scientific workers'.' The pool would probably be more attractive to such workers if a channel is constructed from it leading to positions in the home country and the Dominions. Experience in the tropics has obvious attractions for young biologists, but after a time they naturally look for positions in temperate climates where they can make homes and bring up their families. The proposed Council might perhaps act for members of the research service in the same way as the employment bureaux of our universities act for their graduates, by helping them to find such positions. The disadvantage to the Colonial Service which would result from the loss of more of its best workers would probably be more than compensated by the increased attractiveness of the Service which would result from such a policy, and the Empire as a whole would certainly benefit by it.

At the present time, when official appointments are made, preference is given to candidates with records of service in the War. In future, perhaps we may see advertisements announcing that preference will be given to candidates who have served in other parts

of the Empire.

The Colonial Conference also recommended that the proposed Council should act as "a clearing house for information". The problems of the Empire are similar to those of other parts of the world, so that the necessity of a special imperial bureau of information seems scarcely apparent in view of the existence of the International Institute of Agriculture, which is "a clearing house for information" for the world. At the present time the number of research workers in the British Empire who regularly see the abstracts prepared by the International Institute is probably only a very small proportion of the whole. They

should surely be supplied to every agricultural research station. At present they are generally to be tound only in the central libraries in the capital cities.

Abstracts are of course chiefly valuable to a research worker as a guide to publications bearing on the problems which he is investigating. Some organisation for supplying him with copies of the papers he desires to consult would be of great benefit to the isolated worker, who cannot afford to subscribe to a large number of journals on the chance of seeing papers of interest to him. An Imperial organisation for this purpose should surely receive the support of all the Governments of the Empire.

W B. ALEXANDER.

Croydon, Sept 26

#### An Unusual Case of a Natural Graft.

Some months ago a large elm tree (*Ulmus campestrus*) growing on the grounds of this station was blown down. When it was being sawn into blocks recently an interesting structure was observed. This was so unusual as to be considered worthy of notice.

The diameter of the tree was about three feet, and, judging by the number of annual rings, the age of the tree was in the region of one hundred and twenty years. At a point in the middle of the trunk and about four feet from the ground a distinct cavity was noticed. On careful examination it was found to be a definite air-space. On either side was a protoxylem area—what is technically called a crown. The accompanying photograph (Fig. 1) illustrates the appearance of the trunk, where there were two distinct protoxylem areas.

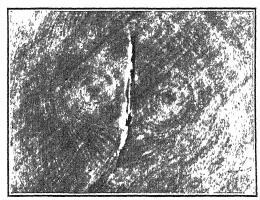

Fig. 1—Two similar 'crowns' and a bark-lined enclosed cavity within the trunk of an elm tree

The distance between the crowns was roughly five inches, and the width of the slit was less than a quarter of an inch; its length at the longest portion was ten inches, and it extended some two feet vertically in the trunk. There were fifteen annual rings between each of the crowns and the cavity. Above and below that region the stem was quite normal.

The cavity was lined with bark which had retained

its normal appearance.

What appeared to have happened was that the tree, while still young, had, for some reason, forked equally, perhaps the terminal bud had been injured and the two forks had grown apart for some years until each was fifteen years old. Previous to this something had caused the two forks to anastomose, and the subsequent growth of the tree had enabled the cambial activity to form a solid xylem cylinder round the portions of the two forks which had not fused together. So far as one could judge, great pressure had been brought to bear on the inner

halves of the two forks, since the enclosed portions of the bark were, as can be seen in the illustration, quite straightened out. There remained only a thin lens-shaped cavity in the middle of the trunk. This cavity was lined, as has been noted, with bark, which had preserved its structure during the hundred odd years it had been enclosed. The sap-wood immediately below this bark had long since lost its function, and had assumed the appearance and, presumably, also the properties of the heart-wood

Nothing can be found regarding the history of the tree, and it would be interesting if any readers of NATURE could suggest how the rejoining of the forks came about, if that be what happened. There was nothing to suggest that it had been brought about artificially.

JOHN CALDWELL.

The Scottish Plant Breeding Station, Craig's House, Corstorphine, Midlothian, Sept. 1.

#### X-Ray Diffraction in Liquids.

The experimental studies described in a previous note in Nature (April 23, p. 601) have been continued by one of us (C. M. Sogani) and the structure of some thirty-five liquids has been studied by X-radiation. The present note indicates briefly some of the outstanding results of the investigation.

The twenty aromatic liquids examined indicate a remarkable variation of the structure of the diffraction halo with the form, position, and mass of the substituent groups which replace the hydrogen atoms in benzene. Ortho-, para- and meta-compounds are

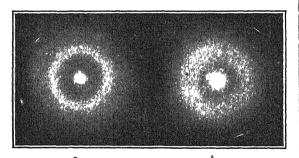

Fig. 1.—Diffraction haloes a. Amiline, b Nitrobenzene

readily distinguished by their X-ray liquid haloes. When the benzene ring is loaded in an unsymmetrical manner, there is a broadening of the halo, which is the more striking the heavier the mass of the substituent group. The research furnishes numerous examples of this effect, a striking illustration being the difference in the haloes due to aniline and nitrobenzene respectively (Fig. 1 (a) and (b)). In several of the liquids, the halo becomes doubled, a good example being that of mesitylene, where the two rings are of nearly equal intensity.

The aliphatic liquids examined include several of the paraffins, some alcohols, and an extended series of the fatty acids ranging from formic acid up to brassidic acid, which has a chain of 22 carbon atoms. The results confirm the prediction of Raman and Ramanathan (Proc. Ind. Ass. Cult. Sc., vol. 8, p. 154; 1923) that with such asymmetrical molecules, we may have more than one halo, the sizes of which correspond to different special configurations of neighbouring molecules relatively to each other in the liquids. The most striking illustrations of this are furnished by acetic acid and glycerine, each of which gives two haloes, corresponding respectively to the mean distance between neighbouring molecules

which he side by side and those which lie end to end. With very long molecules, however, only the former type of halo appears on the plates, and its size, as expected, is found to be independent of the length of the carbon chain. With the earlier members of the aliphatic series, noticeable variations appear both in the size and the character of the halo with increasing length of the chain.

The case of liquid mercury, which has also been examined, is of great interest in view of the monatomic character of its molecules, and also in view of the theoretical proof by Raman and Ramanathan (loc. cit; 1923) that the X-ray scattering by liquids at small angles would be determined by the compressibility of the liquid. Mercury has the smallest compressibility of all known liquids (3 9 × 10<sup>-12</sup>), and in agreement with the theory of Raman and Ramanathan, it is found to give a halo with a sharply defined inner margin and a very clear space within.

Further details will be found in papers appearing in the *Indian Journal of Physics*. C. V. RAMAN. C. M. SOGANI.

# The Influence of Insoluble Materials on the Physical Properties of Liquids.

BAKER in his recent presidential address before the Chemical Society (Jour. Chem. Soc., 131, 949; 1927) directed attention to some interesting observations on the changes in the vapour pressure and the surface tension of a number of liquids brought about by the presence of insoluble foreign materials. Charcoal, thoria, platinum black, and finely divided nickel, materials already well known for their power of catalysing chemical reactions, were used, and he found that they brought about a change in vapour pressure, increasing with time to a constant value and, furthermore, that whilst heating increased and cooling diminished this difference it gradually returned to the original maximum. Baker attributed these changes to alterations in the complexity of the molecular association of the liquid with the establishment, eventually, of a new equilibrium. It appeared to the present writers that any change in the degree of association must necessarily be accompanied by a more or less corresponding alteration in the density of the liquid, and it seemed to be desirable to apply the delicate method of density determination now available (Robinson and Smith, ibid., 129, 1262; 1926) to the elucidation of this question.

As a result of the preliminary experiments of this investigation, in which water and ethyl ether were used, it appears to be established that considerable alteration in density occurs when these liquids, at 15°-20°, are brought into contact severally with catalysts. The density of water at about 14°·1 in contact with carbon was found steadily to increase,  $+0\,000080$  in 48 hours,  $+0\,00019$  in 96 hours,  $+0\,00020$  in 150 hours, at which value it appeared to be constant. With ethyl ether and carbon, changes of greater magnitude were recorded, the increase in density at about  $14^{\circ} \cdot 8$  being in this case +0.0009 in 18 hours, +0.0011 in 42 hours, and +0.0013 in 90 hours, this value being the same after 130 hours. Water at about 18° 5 m contact with thoria showed first a depression of -0.00017 after 24 hours, -0.00002after 48 hours, followed by an increase above normal density of +0.00001, after 96 hours, +0.00011 after 192 hours, and +0.00015 after 209 hours. It is interesting to note that with this catalyst the change m density at about 23°3 showed a much greater initial drop, namely -0 00040 after 24 hours, while the final increase above normal density after 209 hours was only  $\pm 0\,00004$ . The actual change in density between the first and last reading was, however, approximately the same, namely,  $\pm 0\,00032$  and  $\pm 0\,00044$  respectively.

Further work on this subject with other liquids in contact with a variety of surfaces is being actively undertaken and will form the subject matter of a detailed communication to be published elsewhere, meanwhile it seemed to be desuable that these results, substantiating as they do those of Baker, should be briefly indicated

#### Water-spouts and Tornadoes.

When at Frinton recently I was interested to notice a series of whirls like water spouts on a small scale forming on the beach. The smooth, sandy beach at Frinton is protected by a series of low wooden groynes consisting of planks supported at intervals by posts some nine inches square driven into the sand. The planks rise to about a foot above the sand and the posts project somewhat more, as shown in the sketch (Fig. 1) The wind

was blowing up the beach slantwise to the groynes in the direction of the arrow, and in the corner between each post and groyne a perfect little tornado or water-spout was formed. The breaking waves were throwing up foam which was trapped in the shallow pools behind the posts, and this foam was whirled round and lifted into the air by the eddy, the foam thrown by each successive wave being quickly carried away over the groyne. Thus far the phenomena described scarcely call for comment, as the wind blowing round the post would, naturally, cause an eddy in the corner, but the remarkable fact was that the eddies were of such violence that not only foam but drops of water were lifted and, at times, a raised cone of water was visible in the centre which appeared to be at least \frac{1}{2}-inch high. Where did the suction come from?

An outstanding problem connected with waterspouts and tornadoes is the means by which the suction is maintained at the top. The centrifugal force will prevent inflow at the sides, but the whirl cannot be endless, and it has always been a matter for conjecture why air does not flow in from the end and destroy the eddy. Mr. F. J. W. Whipple some years ago suggested that cloud pendants, a similar type of phenomenon, might always occur in pairs, each pair being joined above the clouds and forming a single vortex both ends of which rested on the ground. There seems some difficulty in accepting this view, and the miniature water spouts at Frinton were certainly each self-contained. It is very difficult to see what force at the top balanced the suction, which was clearly shown at the bottom by the raised cone of water. The wind was of Beaufort force 4 or

perhaps 5, it can scarcely have exceeded 15 miles per hour just above the surface of the sand. If this wind passed over an orifice of the most favourable shape it could not produce a suction equal to \(\frac{1}{2}\)-inch of water. The matter might repay further study at Frinton or elsewhere.

Frinton or elsewhere.

Mr. W. Hayes, of the Meteorological Office, has kindly made from my description of the occurrence the sketch which illustrates this letter.

# Early Experiments on Ultra-Filtration.

A PAPER by Wilibald Schmidt, entitled 'Experiments on the Velocity of Filtration of Different Liquids through Animal Membranes" (Ann. der Phys. u. Chem. 99, p. 337; 1856), records an observation which appears to have escaped the historians of colloid chemistry.

The author states that the concentration of the filtrate was compared with that of the original liquid and was found to agree with it when the solutions filtered contained sugar or salts. He then continues: "A different behaviour was shown by solutions of gum arabic and of white of egg. which gave perceptibly less concentrated filtrates, although the solutions had previously been filtered; the former repeatedly through linen, the latter through paper."

This demonstration that an animal membrane is

This demonstration that an animal membrane is much less permeable to colloids than to sugar or salts antedates. Thomas Graham's papers on dialysis by five or six years. Schmidt's procedure, however, is really what is now called ultra-filtration, namely, the separation of colloid particles from the dispersion medium by means of a suitable septum, generally a gel (C. J. Martin, 1896).

Schmidt did not follow up his observation, but confined himself to studying the rate of filtration of true solutions with the view of testing whether it agreed with Poiseuille's law EMIL HATSCHEK.

10 Nottingham Mansions. Nottingham Street, W.1. Sept. 24.

#### The Sources of Supply of Vitamins A and D.

Messrs Rosenheim and Webster, in their very interesting letter to Nature of Sept 24, have suggested that it should be possible to make margarine into "a perfect biological substitute for butter" by incorporation of a suitable content of the vitamins A and D. It would appear from this communication and from other recently published statements that it is not generally known that this problem has actually been solved, and that to-day it is possible to purchase margarine containing regular and uniform quantities of both vitamins of the same order as the quantities found in butter

Researches carried out in our laboratories have led to the development of a large-scale method of obtaining from cod-liver oil a palatable extract containing in highly concentrated form the vitamins A and D, and it has been found possible to incorporate this concentrate in margarine without loss of vitamin efficiency. The potency of the concentrate has been established by colorimetric and biological tests, and extensive feeding trials have shown the vitamin margarine to be equal to butter in its power to promote calcification and restore growth in rats fed on a deficient diet. We shall be glad to send samples of these products to any scientific worker who may be interested in the subject.

P. W. Tainsh.

Research Laboratories, Port Sunlight.

# Metallurgical Photomicrographic Apparatus.

AS a result of the important advances that have been made in Great Britain in the design and production of optical elements for the microscope, it may be claimed that microscope lenses are now being made in England equal, if not superior to, any made abroad The excellence of an optical instrument such as the microscope depends, however, not on the perfection of its optical elements alone. Mechanical arrangements must be provided by means of which these elements may be held in definite relation to one another without shake and be capable of adjustment in a manner which is It is well known, for convenient to the user example, that any lack of true centration in the optical parts or of perfect alignment in the optic axis of these parts produces more serious deterioration in the resulting micro-image than does almost any other single factor. The possibility of such deterioration can largely be prevented by proper attention to the details of mechanical construction and design.

An examination of four modern types of metallurgical photomicrographic outfits at present in use, three of British and one of Continental manufacture, gives examples of the variations in construction and design adopted by different manufacturers in their attempts to fulfil the mechanical requirements. In each case the various parts are supported in such a way as to be capable of moving along an optical bench In the instrument by R. and J. Beck, Ltd, and also in that by James Swift and Son, Ltd., this bench consists of an elongated triangular prism machined on its two upper V-shaped saddles, carrying the various optical fittings, slide on this prism If the inner surfaces of the V were machined so as to make accurate contact with the corresponding slide surfaces of the triangular bar at every part of its length, freedom of movement of the saddle along the prism and accuracy of adjustment might be obtained. It is, however, impossible to machine these surfaces to the required degree of accuracy to avoid shake. A certain manufacturing tolerance is necessary both on the angle of the V and on the angle of the prism. A deviation from the geometrical form is thus produced, and consequently, when the saddles are clamped, rocking or rotation takes place and the alignment is disturbed. is thus impossible on such a bench to make the accurate adjustment necessary in an optical system designed for critical work.

These defects would not occur if kinematical contacts were adopted instead of plane sliding surfaces. This system, the advantages of which have for long been recognised in theory, has been adopted by some of the most progressive manufacturers of scientific instruments; but its adoption in microscope manufacture has not been effected on any large scale. In accordance with the system the correct method of designing the saddle is, as has been suggested by Prof. Alan Pollard, to allow it to make contact at three points on one surface, and at two points on the other sur-

face, of the slide. This restricts the freedom of movement of the saddle to that of sliding along the length of the bench. If the last two points make contact along a line parallel to the axis of the slide, the saddle will automatically fit the bench not-withstanding slight inaccuracies in its machining. With such a saddle no alteration of its position is produced as a result of its being clamped to the bench

In the Continental apparatus referred to above, which is made by Reichert of Vienna, the essential part of the optical bench consists of an openwork metal girder, in bridge form, suitably webbed to secure rigidity The girder is supported at each end and fitted with four levelling screws. Along the whole length of the upper surface at one edge is a plane machined surface The upper edge parallel to this is triangular in section with machined The base of the stands carrying the optical parts have, at one side, a V-shaped groove which fits into the triangular prism of the bench and, at the other, a plane machined surface which slides on the flat machined surface of the girder. A bench of this design, though not perfect, represents an improvement on the triangular bench of the other instruments There is a span of about 4 inches between the centre of the V and that of the plane sliding surface of the base of the carriers, and thus any displacement of the optical elements due to inaccuracies in the machining of the surfaces is considerably less than in the case of the single triangular bar.

In the fourth apparatus, made by W. Watson and Sons, Ltd., the optical bench consists of two metal tubes, cylindrical in section and supported on three brackets. The carrying-pieces rest on these bars, which make contact with the sides of two V-shaped machined grooves in the lower surface of the base of the carriers. In order to ensure accurate adjustment in this case, not only must the grooves be accurately machined, but also the tubes must remain definitely parallel and in one plane. This condition is not easily maintained when the apparatus is in use.

The microscope in each of the outfits examined was of the Le Chatelier type, which is now so frequently used for metallurgical purposes. The object-glass points upwards and is immediately below the stage on which the specimen is placed. In the Beck and the Swift instruments the rack which supports the stage is directly fixed on one side of the stage. The weight of the overhanging stage and of the object placed upon it thus tends to produce a sagging of the rack. The longer the instrument is in use, the greater does this sagging effect become, more particularly if heavy specimens are placed on the stage. The tilting of the stage renders it impossible to focus the whole of the field. This tendency for the stage to tilt is avoided in the Watson instrument by having the stage supported by four upright tubes fixed to a plate centrally mounted above the rack which, however, is placed at one side of the upright pillar. The Continental instrument has the rack cut on one side of a triangular pillar fitted centrally in the saddle-piece resting on the girder. The stage is supported from this pillar by three uprights, one of which is divided in order to permit of the insertion of the visual observation tube. This design tends to reduce the sagging of the rack and obviates any tilting of the stage.

In the last-mentioned instrument, and also in the Beck and the Watson, the fine-focussing adjustment actuates the object-glass and is independent of the coarse adjustment and therefore unaffected by the weight of the stage or of any object placed on the stage. In bringing an object on the stage into view, microscope users generally can tell how far they are from the actual image by the appearance of the light in the field of view In order, however, to facilitate this preliminary adjustment, the Continental instrument is provided with a scale fixed to the pıllar with graduations indicating the position to which the stage must be lowered in order to bring the object into focus for an objectglass of a particular focal length This is an instance of the addition of a device which in use may effect a considerable saving of time on the part of

The illuminating tube of this instrument contains the iris diaphragm, the condensing lens system. and a rotary disc having apertures of different sizes by means of which the intensity of the light may be varied. The condensing lens system is capable of being easily moved along the tube, the positions being marked for the two types of illuminators. Slots are provided in the tube for the insertion of coloured glass or a filter-cell illuminating apparatus, with the exception of the lamp, is thus self-contained and the tube is rigidly fixed in relation to the stage In each of the other instruments the illuminating system is fitted on a separate small optical bench, rectangular in section, supported on a saddle-piece on the main bench. Each item is mounted separately and, while this may permit of greater flexibility, there is at the same time greater possibility of lack of alignment and more trouble in attaining accurate adjustment

The camera supplied with the Reichert outfit is provided with a reflex focussing arrangement by means of which the rays can be deflected on to a focussing screen at the side of the camera. This enables the operator to control the image on the focussing screen from his seat at the microscope. An observation lens carried on a bracket on the camera-stand permits of the image being conveniently examined as a whole. In the Beck instrument the image to be photographed can be projected on to a special white disc. method has the disadvantage that the room must he dark if the image is to be properly examined Better definition of detail can be seen, however, on the white disc than on the ground-glass screen.

Since the study of the macrostructure of metals is now demanding considerable attention, it is very convenient if the camera of the photomicrographic outfit can be used for this purpose. Photographs

under low magnification are frequently required of, for example, fractures, groups of flaws, very coarse structures, segregated areas, or of large crystals in ingot sections. The Reichert apparatus is the only one of the four referred to above which has a complete arrangement for macrophotography as an integral part of the apparatus The illuminating system is mounted on a small horizontal prismatic bar pivoted at the back of the optical bench. The object is placed on a small pivoted swing-out stage which can be tilted and adjusted for height. The surface to be photographed can be either in a vertical or in a horizontal position In the former case either direct or oblique illumination may be used, focussing being effected by rack and pinion adjustment of the front of the In the latter case the image is focussed by vertical adjustment of the object stage. The light is directed obliquely on to the object by means of a mirror, the rays which produce the image being deflected into the objective by a prism attached to it. These macrophotographic appliances are always in position ready for use and can easily be brought into operation at any moment instead of the camera.

The four instruments differ in other details, to some of which the user may attach importance because they suit the particular method of working that he adopts There are also certain accessories which may be fitted as additions to the various instruments for different purposes The essential differences between the four instruments have, however, been mentioned The V-and-plane type of optical bench of the Reichert apparatus offers greater possibility of accurate adjustment of the optical parts than does the triangular bar or the parallel bar type of bench used in the other instru-The mounting of the elements of the illuminating system separately as in the three British instruments provides a wide range of adjustment, but objection may be offered to the method of mounting them on a bar that is rectangular in section The design of the coarseadjustment rack in the Reichert instrument, as compared with that of the other instruments, is such as to minimise the danger of tilting of the stage when in use. The Reichert apparatus has the additional advantage that the mirror arrangement and the magnifying lens for the examination of the image to be photographed, and also the auxiliary appliances for macrophotographic work, form an integral part of the main apparatus would thus seem from the above considerations that, of the four instruments examined, the Reichert apparatus is the most complete and most nearly meets the requirements as regards mechanical design.

The prospective purchaser of a metallurgical photomicrographic outfit will obviously seek for that type of apparatus which will enable him not only to obtain the best possible results from the optical elements at his disposal, but also to obtain these results with the minimum expenditure of time and effort. The efficient production of such an apparatus involves a thorough familiarity with

the art of photography as applied to metals; a capacity for devising mechanical methods which simplify the process of taking a photograph of a metal section; a knowledge of the principles of scientific design and the ability to apply these principles in the mechanical devices employed, and the use of modern methods of precision manufacture and inspection. This obviously involves team work—the co-operation of user and producer. On the latter rests the responsibility for ensuring that the resulting instrument is sound in construc-

tion and design Sound construction requires the application of the best methods of gauging and inspection of the manufactured components. Intelligent design from the manufacturing point of view tends to reduce to a minimum these costly processes, from the user's point of view it aims at ease in manipulation and efficiency in operation. These are all essential factors in the building of an instrument that is to give entire satisfaction to the user or to find a foremost place in either the home or the foreign market.

# Standards of Book Selection in Science and Technology.1

By Sir RICHARD GREGORY

IN these days of minute specialisation in science and technology, and of a multitude of books, both general and specific, the problem of selecting the most worthy and suitable works for a library is so difficult that some librarians give it up in despair, while others are content with a solution of it which satisfies their needs and yet does not conform to any particular postulates or propositions bearing upon the principles of selection. As a matter of fact, there are no definite or accepted standards by which the worth of such books can be accurately measured, but the same comment might reasonably be made of works in any other branch of literature — fiction, art, history — with which libraries are concerned. Of the thousands of works of fiction published, what determines their admission to or exclusion from the shelves of public or other libraries? Chiefly the reputation or authority of the authors. So it must be with books on science and technology. When an author is known to have devoted particular attention to the subject of his book, then the work is obviously one to be given serious consideration A careful compilation may be just as useful an addition to a library, but it cannot have the same authority and therefore belongs to a different category.

There still remains, however, the practical problem of deciding what books are by original authorities and what by writers without the particular knowledge which gives distinction to a scientific or technical book. What librarians would probably like is a monthly list in which such books were grouped in classes of say A, B, and C, according to their importance, but the difficulties in producing such a list are almost insuperable. Failing this, such a list as the "Technical Book Review Index," issued quarterly by the Technology Department of the Carnegie Library of Pittsburgh, provides a most helpful guide to the selection of books on pure and applied science. The Index is arranged in alphabetical order according to authors' names; and it gives extracts from reviews in scientific, technical, and trade journals expressing the scope and value of the works mentioned. It is not supposed that reviews furnish an infallible index to works of

 $^1$  Paper read at the fourth conference of the Association of Special Libraries and Information Bureaux at Cambridge on Sept. 25.

outstanding importance, but they do provide a practicable source of information, and a useful purpose is served by bringing them together, as is done in the "Index" of the Carnegie Library

The recent "Report on Public Libraries in England and Wales" recognises that good and necessary books declare themselves slowly, and that there is an insufficiency of competent critics to help the librarian in his task. The Public Libraries Committee says in this Report

Attempts to provide a guide for book selection for librarians, some fairly good, have from time to time been made, but for various reasons have failed. Possibly the task is too difficult, and consequently the present method of book selection in most libraries is and can be little better than the primitive method of trial It cannot be expected that librarians or book selection committees, however competent as literary critics, should be qualified judges of all scientific and technical publications, and reliable reviews of these are usually the most difficult to find and the most belated in appearance. Librarians would, we believe, welcome assistance in the choice of books by the issue of authoritative surveys of new publications by a panel of competent judges. It is, however, essential that such surveys should not be too long delayed, and it is not easy to find qualified critics who are able and willing to devote themselves to the prompt evaluation of new books. Such surveys are, however, issued by the American Library Association, and are found helpful by librarians in America.

There is no central organisation in Great Britain which affords the same kind of competent guidance in the selection of books as that given by the American Library Association, Chicago. Each month a tentative list of all books received during the previous month is sent to representative librarians, who vote on books they have personally examined, and these votes, together with references to notices of the books in leading journals and opinions from a panel of voluntary workers, are considered by a staff which reads the selected books and prepares notes upon them for subscribers to the list. In the case of new editions (especially of scientific and technical books) libraries are advised whether the alterations are sufficient to make it desirable that the older editions should be replaced by the new.

Here, then, is a system which at any rate provides a sieve by which the more substantial works

No. 3023, Vol. 120]

are separated from those which pass through the The Public Libraries Committee suggests that the Carnegie United Kingdom Trust, which has done so much for library work and organisation, might very appropriately promote the establishment of a similar scheme in Great Britain, and we are sure that librarians would welcome such an experiment Another plan would be to make the Science Library at South Kensington responsible for the selection of scientific and technical books of outstanding importance. The Public Libraries Committee contemplates that this library will be the principal source on which the Central Library will depend for the supply of books needed by research students in science, and the facilities \_it possesses or could acquire for selecting the best works on science and technology might readily be made available to libraries generally.

The task of deciding what are the best books in any subject is, however, one which no individual or institution can lightly undertake. Lists alone are not sufficient, and if they are annotated then great responsibility is placed upon the judges unless the comments are purely explanatory. There must be different standards for different types of book, and no single touchstone will be sufficient to separate the gold from the baser metal in all the classes. For our present purpose we may distinguish three groups, namely (1) popular works, (2) text-books, (3) works of reference, to each of which a different standard of selection

must be applied

(1) Popular Science — Popular books on scientific and technological subjects vary from childishly simple essays to closely reasoned accounts of the most recent additions to knowledge. They may, however, be divided into two main classes distinguished both by authorship and style. One class consists of books by writers who have the literary art of attractive presentation of scientific fact or conception. They are able to state the case for atoms and electrons just as clearly as for cells and chromosomes. They are not expert witnesses but counsel having the faculty of seeing essential points and expounding them to the court. Every librarian knows the names of some authors of this type who are popular with their readers. The works are often superficial, and scientific critics may regard the treatment as unsatisfactory, yet they serve a purpose in leading readers into realms of knowledge previously unknown to them.

Between this type of popular book with its everyday vocabulary and sentimental appeal and the book by an exponent who knows his subject by first-hand experience there is usually a great gap. Few original investigators in scientific fields are capable also of presenting them in attractive and intelligible language. They use technical words and terms which convey no clear meaning to general readers, and their books are for study rather than for reading as recreation. It is impossible to set a definite standard of suitability for books of this kind or for those of the more elementary type. All that can be done is to be

guided by experience as to authors whose works are most popular with particular groups of readers.

A list of one hundred Popular Books in Science" is issued by the American Library This list was prepared by a special Association. committee of the Washington Academy of Sciences; and it gives, in addition to full bibliographic particulars, a descriptive paragraph about each book and notes upon the various groups of scientific subjects under which the books are classified. The list, though a very useful guide to sound popular works in science, is not altogether satisfactory from our point of view It certainly includes about forty English books which are available from publishers in the United States; but there are, of course, many popular scientific books which have never been taken over in this way, and these seem to have been left out of consideration.

The principles followed by the Committee in compiling the list are, however, of general application, and are stated as follows:

Would the average reader who uses a public library, after reading the book in question, read it through to the end and come back to the librarian for another on the same subject? Such a book should be included. Or would he lay it down after a little while and turn to some other kind of book as being more interesting and not return to the subject again? Such a book should not be included, however accurate, thorough, and complete it might be from the standpoint of a specialist.

It is also desirable that the book should not be professedly a text-book, nor should it be written in text-book style; that is, it must not be a book intended primarily for the seeker after information regardless of whether the information be interesting reading or not. It is perhaps needless to add that it should have been written by an author who knows his subject thoroughly and should not be so old as to

be obsolete in its facts and speculations.

(2) Books for Students — Text-books for use in school or college belong to a different category from that of popular works for general readers. Their function is not so much to inspire as to instruct, and they sacrifice the flow of language to concise and precise statements of ascertained fact and established principle. The usual standard by which a text-book is measured is that of a proximate or ultimate examination. In Great Britain a school text-book which has no relation to examination requirements has little chance of success however original it may be; indeed, it may suffer by the very originality of its qualities. A list of the best text-books in any subject, therefore, would differ according to the point of view adopted—whether that of original and stimulating treatment or that of preparation for particular examinations. There are few books of the former type and many of the latter. In the text-book field the name of an author does not carry so much weight as it does in more popular literature, and new authors are continually competing with old for first place. Each teacher or professor has his own idea as to what are the best books for his students, so that any list of text-books published by a body representing the teaching profession tends to become a list of nearly all books available, with no comments on their value

Two such lists are published, by the Science Masters' Association and the Association of Women Science Teachers respectively The lists are useful catalogues of titles of class-books and works of reference upon various branches of science, but a librarian or student wishes to know which are the best two or three books in each of the groups and neither list affords that kind of guid-In almost any usual school subject of scientific study, there are twenty or more 'best' books, and only individual preference selects one rather than another It may be doubted whether librarians should include such books on their shelves, or limit themselves to text-books of an advanced type which students may not be able to afford to purchase or which may be of service for reference

The only sound standard of school-book selection is that of successful experience, and if such books are included in a public library, probably the best plan is to communicate with teachers of science and technology in the secondary and technical schools of the district as to the books in actual use. This may be an unsatisfactory course to follow, but it is preferable to placing upon a librarian the responsibility of selecting the best text-books from scores which are equally serviceable. The tendency in school text-books is towards consideration of everyday things and away from the purely academic attitude, so that some books of this class are as acceptable to many readers as are books written in what is conceived to be a popular style

(3) Standard Works - An attempt is made to

provide a guide to what books are of value to students of science and technology in Sonnen-schein's monumental work. "The Best Books," the third edition of which appeared a few months ago. Three-quarters of the volume comes under the head of science understood in a broad sense, and there are signs by which works of outstanding importance may be distinguished from others. Such a work, however, soon gets out-of-date, and what librarians want is a periodical list in which scientific works are evaluated on a standard plan

Almost every week sees the publication of a number of books on various topics of science and technology, and to decide which are of permanent value and which negligible puts too great a strain upon the capacity of a librarian or a library committee What, for example, determines the works of reference which ought to be in a library and those which may be omitted? Every department of science and technology is now minutely specialised, and for most of the many aspects of them there are special books Probably the chief means by which the worth of these is measured are reviews in leading journals devoted to science and technology, but such notices are often long delayed, and even the best reviewers have different standards of When, however, a work is actually purchased for the library of a leading scientific or technical society, or accepted from one of its fellows, this fact provides positive evidence of its substantial quality. If, therefore, arrangements could be made to compile a monthly list of such purchases, librarians would be provided with titles of works of outstanding importance from which to select what would be most suitable for their reference shelves

### Science and Industry in Australia.

THE Council for Scientific and Industrial Research of the Commonwealth of Australia Research of the Commonwealth of Australia has decided to issue a quarterly journal which will provide a means of disseminating general information respecting Australian scientific problems and the scientific research work in progress throughout the Commonwealth. In a foreward to the first number of the new Journal of the Council for Scientific and Industrial Research 1 (August 1927), the Prime Minister (the Right Hon. S. M. Bruce) stresses the importance of making the best possible use of the relatively small personnel which is available for the scientific investigation of Australian problems. To this end, a Trust Fund of £250,000 has been created for the use of the Council during the first few years of its existence, while the interest on a further sum of £100,000 will be applied to the training of research students. particularly in the biological sciences On the manufacturing side, the co-operation of the Council with the British Department of Scientific and Industrial Research will be facilitated by the recent visit of Sir Frank Heath to Australia

<sup>1</sup> Edited by G. Lightfoot, and published by the Government Printer, Melbourne, at 5s. per annum, post tree

(NATURE, 117, 460, 697; 1926), and it is hoped that co-operation in agricultural activities will be considered at the Imperial Agricultural Research Conference being held in London this month

Sir George Pearce contributes an informative article dealing with the organisation and work of the Council, in which he summarises the progress of investigations on plant problems, irrigation settlement problems, entomological problems, animal pests and diseases, stock nutrition, forest products, the preservation and transport of foodstuffs, fuel problems, etc. In addition to this general treatment, special articles are included on "The Commonwealth and Agricultural Research" (Prof A. E. V. Richardson), "Animal Nutrition Problems" (Prof. T. B. Robertson), and "The Biological Control of Prickly Pear " (A. P. Dodd) There are also reports on co-operative research in the wool industry, and on the Australian meat industry (freezing of beef), together with notes on the investigation and eradication of poisonous plants, astronomical work in Australia, the Australian Radio Research Board, and other matters.

The enormous losses occasioned by imported plant and animal pests have shown the need of

submitting such pests to scientific control, and their investigation figures largely in the work prosecuted under the regis of the Council Public opinion in Australia is now fully alive to the economic significance of work of this kind so that even the construction of the transcontinental railway was not undertaken without the introduction of precautions against the spreading of sparrows and starlings from the eastern States into Western Australia

The most important plant problem is undoubtedly presented by the prickly pear (Opuntia), which covers some sixty million acres in Queensland and New South Wales, with an annual rate of increase of about a million acres The two mam pest pears are O inermis and O. stricta, and the remarkably rapid spread of the former species in Australia is regarded as one of the botanical wonders of the world." Eradication by mechanical or chemical methods is usually impracticable on account of the density of the growth and the low value of the infested land. Efforts have therefore been concentrated upon the application of biological control, and the striking results of introducing such American prickly pear insects as cochineal (Dactylopius tomentosus, D. indicus, and newsteadi), boring caterpillars (Cactoblastis cactorum), the prickly pear red spider (Tetranychus opuntice), plant-sucking bugs, etc , have " altered the hopeless attitude from which the control of prickly pear was formerly viewed. There is every reason to believe that, as the insects multiply and spread, the area covered by the pest will gradually diminish, and the land be reclaimed for pastoral and agricultural purposes " Researches are also in progress at the Waite Agricultural Research Institute, South Australia, on 'tomato wilt,' a disease, originating near Melbourne in 1915, which has caused great destruction in all the tomatogrowing States; while in Queensland attention is being concentrated upon two diseases ('bunchy-top' and 'squirter') which have occasioned enormous losses to growers of bananas "The major part of the investigations on bunchy-top, a disease which has practically wiped out the banana plantations in certain areas, has been completed, its cause and the means by which it is spread have been discovered, and recommendations for control have been made to the State authorities."

The development of the Murrumbidgee irrigation scheme has raised problems in connexion with citriculture, viticulture, rice-growing, etc., and these are being investigated in the research stations at Griffith and Merbein; in addition, a soil survey is being conducted under the direction of Prof. J. A. Prescott, of the Waite Institute.

The entomological work is concerned at present mainly with the grass-grub, the buffalo-fly pest, and dried-fruit pests. It is feared that the buffalo-fly, if allowed to spread, may affect the Australian cattle industry even more seriously than the cattle-tick has done; the problem of control is difficult, but a beginning has been made by collect-

ing information regarding this formidable pest from entomologists in the Dutch East Indies, the Philippines, and Hawaii. Another animal pest, of a very curious and embarrassing nature, is the 'flying fox,' a large fruit-eating bat, the depredations of which were recently described in Nature (Aug. 6, p. 189) by Prof. A C D Rivett

Investigations of forest products, which are of peculiar interest in Australia, have been directed largely towards the possibility of utilising indigenous woods in the manufacture of news-print, the annual import of which exceeds 100,000 tons. Those pioneer workers on Australian forest products, R T. Baker and H G Smith, pointed out some years ago that certain species of Eucalyptus were suitable for this purpose; recent work carried out under the auspices of the former Institute of Science and Industry, and extended by the present Council, has done much to establish the economic possibility of preparing from such sources a mechanical pulp, suitable for blending with chemical pulp of the same origin, in the production of news-print There are also prospects of utilising Australian woods as the raw material of high-grade celluloses, suitable for the manufacture of artificial silk Further, the pulp from Pinus insignis, an imported pine which grows very rapidly in Australia, has been found to lend itself particularly to the manufacture of kraft paper.

For many years it has appeared paradoxical that Australia, which is exceptionally rich in plant astringents, should import tan-bark and tannin extracts from South Africa, from the Australian point of view the paradox becomes painful when it is realised that a good deal of this imported material is derived from varieties of wattle originally cultivated in South Africa from Australian seed! It appears from the Journal that a comprehensive survey of Australian sources of tannin has been accomplished, and that a small extraction plant has been erected for the investigation of barks from suitable species of Acacia and Eucalyptus, and also from mangroves. To these should certainly be added a number of species of Callitris, notably C calcarata, which is so widely distributed on waste hilly land and 'pine ridges' throughout the eastern States of Australia. In spite of such investigations, one fears that the economic production of tannins in Australia will continue to be handicapped by the disparity between the wage accepted by South African bark-strippers and that required by the Australian 'bush-whacker' for the

The almost complete dependence of Australia on other countries for the supply of liquid fuels has led to a consideration of the low-temperature distillation of coal and shale, but on account of the general attention which is being devoted to this matter in other countries, it is not considered justifiable by the Council to undertake researches of the kind in Australia. No doubt current work on the utilisation of brown coal as a basis of liquid fuels will be followed in Australia with

equal interest. An inquiry is also being made into the reasons underlying the economic failure of the Australian shale-oil industry. Researches on the production of power alcohol are at present limited to experiments which are being conducted under the supervision of Prof. N. T. M. Wilsmore, dealing with the hydrolysis and fermentation of the commoner Australian hardwoods.

It is evident from a consideration of this interesting new publication that the Commonwealth

Council for Scientific and Industrial Research is making encouraging progress with the multifarious problems presented by this isolated and fallow land-mass of the southern hemisphere, which until recently has remained free from the disturbances and developments following in the train of permanent civilised settlement. The future record of the Council's activities should be full of interest to workers in all branches of science.

John Read.

# The Centenary of Marcelin Berthelot.

RENCH chemists will be supported by their colleagues of many nations in the forth-coming celebration of the centenary of the birth of Pierre Eugène Marcelin Berthelot, the famous Parisian chemist whose researches, particularly those dealing with thermochemistry and with the synthesis of organic compounds, were as revolutionary—rather, as evolutionary—in their effect on the aims and outlook of chemistry as those of Lavoisier.

Berthelot was born in the Place de Grève, now Place de l'Hôtel de Ville, on Oct. 25, 1827, and died, also in Paris, on Mar 18, 1907 The centenary celebrations commence on Sunday evening, Oct. 23, with a reception of the members of the official delegations in the Salons of the Sorbonne. On the following day the guests will be present at the opening of the exhibition of Berthelot souvenirs in the Faculty of Pharmacy, and will visit the savant's monument and laboratory at the Collège de France. There will follow a reception at the Hôtel de Ville, and a commemorative assembly at the Sorbonne.

On Tuesday, Oct 25, the proceedings will commence with a ceremony at the Panthéon; the delegations will also attend a banquet at the Palais de Versailles and a soirée at the Théâtre National de l'Opéra. On Wednesday, Oct. 26, the foundation-stone of the "Maison de la Chimie" will be laid, lunch will be taken at Chantilly, there will be a reception by the Institut de France, and the celebrations will terminate with a reception in the Palais de l'Élysée by the President of the French Republic. The arrangements are being made under the presidency of M. Paul Painlevé. The "Maison de la Chimie," which is to be erected in Berthelot's honour, will provide a centre at which various international committees may establish their bureaux; it is intended also to provide a library, and suitable accommodation for gatherings of an international character

Berthelot's contribution to scientific progress was amazing in its extent, marvellous in its accuracy, logical in its prosecution, clear in its expression, and far-reaching in its effects. Only in 1843, Berzelius had expressed little hope of the synthesis of more than a few exceptional organic compounds; the barrier between mineral chemistry and the chemistry of living things was still not only real, but also apparently permanent. Berthelot's synthesis of ethyl alcohol, formic acid, methane, ethylene, acetylene, and benzene de-

stroyed that barrier with a completeness which has been emphasised by the subsequent systematic architecture and construction of the wonderful edifice of synthetic organic chemistry as it exists to-day. Evidently Berthelot realised something of the proportions of that edifice when he said "Le domaine où la synthèse chimique exerce sa puissance créatrice est plus grand que celui de la nature actuellement réalisé." Out of an observation of the sluggishness of the formic acid synthesis there developed an extensive series of investigations on thermochemistry, a subject in which considerable progress had already been made by Thomsen and others; recognition of the principle of mass action can be traced to Berthelot's work on the interaction of glycerol and acids; the fixation of nitrogen interested him, and it is noteworthy that, in the face of considerable criticism, Berthelot asserted that free nitrogen could be assimilated by plants. He was also the first to ascribe this power to the activities of bacteria in the soil. In the latter half of his life, Berthelot took an active interest in public affairs. Thus, during the siege of Paris in 1870, he became president of the Scientific Committee of National Defence, an appointment which led directly to his systematic study of explosives and the theory of explosions, and to a new conception—that of the detonation wave. Later he became Minister of Public Instruction and then Minister of Foreign

The dominant aim of Berthelot's life was the discovery of truth and the service of mankind. It was fitting that the medal struck in his honour on his seventy-fifth birthday should have borne the inscription, "Pour la Patrie et la Vérité." It is quite impossible in these columns to express in any but the most general and colourless terms the debt which human progress owes to Marcelin Berthelot. Those who, without studying the great number of his original papers, desire to know more both of the man and of his work would do well to refer to Prof H. B. Dixon's Berthelot Memorial Lecture (Journal of the Chemical Society, 99, 2353; 1911), to a longer notice by M. Émile Jungfleisch (Bulletin de la Société Chimique de France, 1913, 260 pp. separately paginated), to a brief article by Prof. Camille Matignon (Chimie et Industrie, 16, 3; 1926), and to an appreciation by Dr. C Graebe (Berichte der Deutschen Chemischen Gesellschaft, 41, 4805; 1908).

# Obituary.

#### Prof Adrian Stokes

THE death of Dr Adrian Stokes, Sir William Dunn professor of pathology, of Guy's Hospital Medical School, University of London, has robbed pathology, and therefore medicine, of one who, though he had already accomplished much, had not yet reached the height of his powers, and his loss, at the early age of forty, is the more poignant because of the tragic circumstances which sur-

Adrian Stokes was the youngest son of Mr Henry John Stokes, and was born at Lausanne in 1887. There was a strong medical tradition in the family, for many of his forbears had left names to conjure with in Irish medicine. At Trinity College, Dublin, where he graduated in 1910, he early gave promise of brilliance, for he not only gained numerous academic distinctions, but he was also a keen athlete and was a worthy member of one of the strongest cricket elevens that has represented his Alma Mater.

After doing the usual house appointments, Stokes spent eight months at the Rockefeller Institute in New York, and then returned to Dublin where he joined the staff of Prof. O'Sullivan. Henceforth he devoted himself whole-heartedly to the study of pathology and bacteriology, and he had become an expert in laboratory technique when the War broke out in 1914 He at once obtained a commission in the RAM.C. and served in France throughout the War. Although actually attached to a casualty clearing station as a specialist in pathology and bacteriology, Stokes took the broadest view of his duties and responsibilities He equipped his motor cycle and sidecar with an incubator, setting up what was in effect the first mobile laboratory in France, and his work did much to restrict the incidence of typhoid fever in the early days of the War.

Of the original work which Stokes carried out during this time, his investigations into the cause and mode of transmission of spirochætal jaundice was probably the most important. He identified the spirochæte and demonstrated its presence in the bodies and urine of trench rats, a discovery which led to the suppression of what might have become a very serious epidemic. But it was not only in his own particular branch that Stokes did brilliant work. He was the inspiration of the mess in which he lived. Full of energy and ingenuity, he not only lent a hand wherever one was required, but also he tackled the problems of others and applied his knowledge of laboratory technique to solving their difficulties He kept himself up to date in the various new methods of treatment and, as soon as he was convinced of their superiority, he never rested until they had been adopted in his immediate vicinity. 'Brass hats' were to him the means of obtaining what he felt was necessary for the good of the sick, gassed and wounded, and his vehement, but clear and cogent, demands for apparatus, drugs, etc., were very rarely unsuccessful. All this he effected while maintaining his own special department at the height of efficiency. Those who served with him aver that he did more than any other single individual to improve the medical treatment of the troops and to diminish wastage.

On demobilisation in 1919, Stokes was appointed to the chair of bacteriology and preventive medicine at Trinity College, Dublin, but in 1920 he was invited by the Rockefeller Foundation, who had been greatly impressed by his work on spirochætal jaundice already mentioned, to join the West African Yellow Fever Commission It happened that during his visit to Africa very few cases of vellow fever occurred, and his work was necessarily indeterminate

In 1922, Stokes was appointed to the Sir William Dunn chair of pathology at Guy's Hospital Medical School in the University of London, which he occupied at the time of his death. He did much to improve the status of pathology in the School, and he was tireless in his efforts to arouse interest and to stimulate research Intensely practical in his teaching, he succeeded in attracting brilliant students, and, given the time, he would have created a school of pathologists keen to tackle problems whose solutions might lead to advances in medicine

In April of this year Dr. Beeuwkes, the head of the Rockefeller West African Yellow Fever Commission, asked for Stokes's help, for the problem of yellow fever in West Africa was little nearer solution than it had been in 1920. Indeed, it was still uncertain whether it was identical with the yellow fever of South America. The latter disease is carried by Stegomyia fasciata, the common domestic mosquito, and Noguchi has described a leptospira as the causative organism. Stokes obtained leave of absence from Guy's for six months and sailed for Lagos in May. He was not particularly hopeful of succeeding where others had failed, and his first letters spoke of negative results. In July the outlook was brighter, and in the middle of August he wrote that he had succeeded in transmitting the disease from the human patient to monkeys, both by blood infection and through the medium of mosquitoes. No leptospiræ had been found, and he was satisfied that the cause had not yet been isolated. He was then engaged in the microscopical examination of infected mosquitoes in serial section. "It is infuriating to know that one has the virus under one's eyes and cannot see it," he wrote at that time.

Then on Sept. 16 came a cable to say that Stokes was seriously ill He was removed that day to the European Hospital, where he died of yellow fever on Sept. 19. How he contracted the disease is not yet certain, but it would appear highly probable that he infected himself accidentally in his laboratory. Time alone can show the value of his work on the disease to which he fell a victim; but if, as appears certain, he has helped materially towards the discovery of the cause of yellow fever in West Africa, he would not have counted the cost.

In Stokes's public and private life, transparent honesty and sincerity irradiated his every word and every action . outspoken and candid, he never left any doubt as to his meaning and ' to beat about the bush 'was foreign to his nature His energy and his capacity for work were amazing, and all the more so when one remembers that his greatest enemy was insomnia, and that for him five hours As a teacher, was an unusually good night's sleep he preached the gospel of scientific truth with an earnestness born of conviction His students absorbed from him the right critical attitude towards their work, and the best of them became infected with his own zeal for research He was generous to a fault, and many a lame dog was helped over a stile without ever knowing whence his help had come. An Irishman by everything but the accident of his birthplace, he loved his country as deeply as he hated those whom he regarded as being responsible for her unhappy state, which was a source of real grief to him

Stokes died in harness, as he would have wished to die, but his premature death will be widely mourned by all who are interested in the advancement of medical knowledge, and especially by those who were privileged to come into intimate contact with a personality so vigorous, so stimulating, and so kindly

WE regret to announce the following deaths

Prof Syante August Airhenius, For Mem R.S., of the Nobel Institute, Stockholm, from which he received the Nobel prize for physics for 1903, on Oct. 2, aged sixty-eight years

Prof. Willem Emthoven, For Mem. R.S., professor of physiology in the University of Leyden, and Nobel laureate for physiology for 1924, on Sept 28, aged

sixty-seven years.

Dr George Andrews Hill, senior astronomer at the U.S Naval Observatory, Washington, on Aug 29. aged sixty-nine years

Prof. A. Liversidge, FRS, emeritus professor of chemistry in the University of Sydney, on Sept 26,

aged seventy-nine years

Dr H D Thompson, for more than thirty years professor of mathematics at Princeton University, who was known for his work on hyperelliptic functions and on geometry, aged sixty-three years.

# News and Views.

THE annual general meeting of the Australian National Research Council was held in Melbourne on Aug. 25-26. Particular attention was given to the financial position of the Council in relation to present and future work. The offer of the Carnegie Corporation to provide a sum of £5000 as the nucleus of a research fund was accepted with most cordial thanks, and with this sum and more than £1000 available from other sources, such a fund was formally insti-A strong committee was appointed to take action for securing additional contributions from Australian sources, and it is hoped that before long the Council will be in a position to give considerable aid to Australian workers in pure science Amongst several satisfactory reports on the year's work was one from the Anthropology Committee outlining the progress made since the initiation of the Department of Anthropology in the University of Sydney. step followed upon a resolution by the second Pan Pacific Science Congress of 1923 and was made possible by contributions from the Commonwealth and State Governments and the Rockefeller Foundation. The new Department is now in full swing and is taking active steps to organise investigations both on the mainland and on the neighbouring Pacific islands. The following new members were elected to the Australian National Research Council, the total membership of which may not at any time exceed 100: Mr. C. R. P. Andrews (Director of Education, Western Australia); Prof. A. R. Radcliffe Brown (Anthropology, University of Sydney); Prof. A. N. S. H. Burkitt (Anatomy, Sydney); Prof. A. J. Ewart (Botany, Melbourne); Dr. W. A. Hargreaves (Government Chemist, South Australia); Prof. J. W. Paterson, (Agriculture, Perth); and Dr. H. R. Seddon (Veterinary Research Station, New South Wales).

THE Trustees of the Commonwealth Science and Industry Endowment Fund in Australia are this year

making £1250 available in small grants for the assistance of scientific workers in Australia. which will be followed in making the grants will be similar to those which have been proved to be satisfactory by the Department of Scientific and Industrial Research in Great Britain. The Commonwealth Fund has an invested capital of £100,000, and it is provided by Act of Parliament that the interest from it shall be employed for the dual purposes of training students in the methods of scientific research and in providing assistance to persons engaged in research, irrespective of whether their work has an obvious practical application or not. At present, the income is being devoted mainly to the first object, but as time goes on it is expected that an increasing sum will be available annually for distribution in grants.

Prof. J. A Prescott, professor of agricultural chemistry at the Waite Institute, University of Adelaide, has been appointed adviser on soils problems to the Commonwealth Council for Scientific and Industrial Research. Prof. B. T. Dickson, of Macdonald College, Quebec, has been appointed chief mycologist to the Council and will take up his duties in Australia towards the end of the year.

THE interest in the relationship between science and religion, which was revived by Sir Arthur Keith's address to the British Association on the descent of man, has been further stimulated by the sermon preached by the Bishop of Birmingham in Westminster Abbey on Sept. 25, and the opinions of eminent divines thereon which have been collected by the Morning Post. As a further reaction, the Sociological Society, aiming at resolving the conflict in a higher synthesis, has arranged a series of addresses expounding the 'sociological approach' to religion in which a 'higher' science, accepting the data of a 'lower,' will deal with the religious process as a striving after a purpose which renews itself from

White the state of the same

generation to generation in purifying and ennobling man's life in its quest for mastery of self and the environment. The series of addresses will be opened on Oct. 18 by Sir Francis Younghusband, president of the Society, who on this and the succeeding Tuesday will deal with what is termed the 'attack' on religion and the reply, though no actual attack has been made by science. He will be followed on succeeding Tuesdays by Mr Farquharson, Dr. Saleeby, and Mr. V. Branford. The addresses will be delivered at 1.15 p. M. in All Hallows Church. Lombard Street.

THE tornado which caused so much damage and loss of life at St. Louis on Sept. 29 appears to have been a typical example of the most violent of all types of atmospheric vortex Along the narrow strip of country—generally less than a quarter of a mile wide—visited by a tornado, destruction is generally complete, for no building can withstand the enormous pressure exerted by the winds, which are believed to exceed a speed of 200 miles an hour; moreover, the reduction of statical pressure in the central core is so great that buildings, which tend to retain air at pre-existing pressure, frequently burst Tornadoes reach their fullest development in the United States, particularly in the great lowlands east and west of the central and upper Mississippi and lower Missouri valleys. They generally occur to the south or southeast of cyclonic depressions that have, extending southwards from the centre, a pronounced 'trough,' often of V shape, separating warm moist southerly winds from the Gulf of Mexico from relatively cold westerly to north-westerly winds lying farther to the west, and normally arise a little to the east of the line of discontinuity which marks the boundary on the ground between the two wind currents. The tornado is clearly due to instability of moist air. and therefore occurs most often at that time of the year when conditions are most favourable for a steep vertical gradient of temperature, or 'lapse-rate,' that is, in the spring and early summer, when solar heating is becoming powerful and yet the upper atmosphere retains much of its winter coldness; however, unlike the far larger 'tropical cyclone,' it may occur in any month St Louis was the scene of one of the most famous tornadoes of the close of last century—that of May 27, 1896—but the recent storm appears to have been the more destructive of the two

SEPTEMBER was in most parts of the British Isles an even wetter month than was August, the total rainfall in some places being three times the normal. At Kew Observatory the total was 450 inches, compared with 406 inches in August. It is interesting to note that the records of rainfall in London since 1812 show that in two previous years—1852 and 1903—a run of wet months began in June. In 1852 the last seven months of the year yielded 28 08 inches, and in 1903, 26 81 inches, whereas the normal for the whole year is between 24 and 25 inches. In neither of these years, nor in any year previous to 1927, did the combined totals for August and Sep-

tember exceed eight inches, consequently the total of 8.56 inches for the last two months is easily a 'record' since 1812

The immediate cause of the wet weather in September was the persistence of high atmospheric pressure in the neighbourhood of Greenland. This caused frequent cold north or north-east winds over the Arctic Ocean, and these encountered warm south-westerly winds brought up from low latitudes round the anticyclone between the Azores and Bermuda. Such winds carry with them much moisture especially in early autumn, and the interplay of the two currents resulted in the formation of numerous depressions, which were carried eastwards across the British Isles by the upper winds from the west that prevail in temperate latitudes when there is a steep gradient of temperature from south to north Moreover, the persistence of high pressure in the far north tended to prevent Atlantic depressions from wandering up into higher latitudes, and so allowing the Azores anticyclone to make those periodical excursions north-eastwards which are responsible for so many of our spells of dry sunny weather

On Oct. 3, the telephone service between Great Britain and Canada was opened and messages were exchanged by Mr. Baldwin and Mr Mackenzie King and by representatives of the Times in London and in Toronto. It was stated that the conversations were heard very clearly. The route taken by the signals depends at present partly on American land lines From London the signals go to Rugby by land line. whence they are transmitted by radio to Houlton, in Maine, some 600 miles from New York Houlton they go by land line to any Canadian city which is required. Canadian messages are transmitted by land line to New York, thence to Rocky Point, whence they are sent by radio to Cupar in Fifeshire. From Cupar, the signals travel by land line to London. There is no suitable radio station for the Great Britain-Canada service in Canada, and it is stated that no such station is contemplated.

CAPTAIN IAN FRASER complains, in a communication in the Times for Sept. 29, that many of the dwellers on eastern and southern seaboards of England have their broadcast reception spoiled by the Morse signals coming from ships. He does not ask that ships be forced to scrap obsolete apparatus, but he thinks that all new radio equipment for ships should be made so as to operate closely on their own wave-lengths and consequently not trespass on the band of frequencies allotted to broadcasting. It should not be difficult to obtain this by international agreement. Until recently practically all Post Office coastal stations for communicating with ships made use of synchronous spark telegraphy. The average range of stations like those at Seaforth, Fishguard, Niton, Cullercoats, and North Foreland is about 500 miles. With the spark system adopted, only 'broad' tuning is available, and consequently the waves emitted interfere seriously with users of crystal sets. The Post Office authorities are now substituting the more modern and more efficient interrupted continuous wave system of communication for the spark systems. This will be a boon to listeners-in at places like Seatorth and Cullercoats.

In the July number of Electrical Communication, a journal published by the International Standard Electric Corporation of New York, there is an instructive article on "European Telephony as affected by the International Telephone Committee." It is pointed out that the War was followed by the formation of many so-called international organisations which were, however, almost purely European. They cover a wide field of activity in commerce and industry. The organisations are concerned with railways, tramways, electric traction, sleeping cars, production and distribution of electricity, telephony, telegraphy, broadcasting, etc. The formation of these unions is attributed mainly to the idea underlying the creation of the League of Nations. In 1922, Mr. F. Gill first suggested international telephony. The outcome of this was the formation of a Comité Consultatif International—now known as the CC.I. -for organising international telephony in Europe. It was hoped that the C.C.I. would become affiliated with the League of Nations, but when the proposal was made, Germany was not a member of the League and so the C.C.I. was incorporated into the International Telegraph Union. As the Union embraces the whole world, any country can now become a member of the CC.I. on application. Mczambique and the Union of Sovietic and Socialistic Republics (U.S.S.R.) are now members. One of the main objects of the international committee is to secure uniformity of practice, but representatives of private industry are invariably consulted. The committee has also decided to establish in Paris a Master Standard Reference System, to enable the countries of Europe to standardise their telephone apparatus. Another question which has been discussed is the construction of a special type of underground cable for the purpose of interconnecting broadcasting centres in Europe. It is concluded that the C.C.I. has fulfilled and is fulfilling a useful function.

EXCEPTION has been taken by Mr. J M. Crosthwaite, secretary to the Scottish Society for the Protection of Wild Birds, to a "few misapprehensions" which he alleges appeared in a paragraph dealing with the 'death' of the Wild Birds Protection Bill, in our issue of July 23. In a letter to the editor on the subject, he repeats, amongst several criticisms of the Bill which have no bearing on the paragraph in question, the misleading statement against which the paragraph protested, that "this Bill adopted the extraordinary principle of securing protection only for rare birds," while at the same time he admits that for five months, covering the most important part of the year, the breeding season, it prohibited the taking and destroying of all wild birds. Mr. Crosthwaite considers that birds were better off without this Bill, and supports his view by statistics showing that a larger number of species is included under the present County Council orders. But the effective-

ness of the protection is more important than lists on paper, and in a matter of opinion most people will prefer to be guided by skilled naturalists and legislators, such as Viscount Grey of Fallodon, Sir Montagu Sharpe, the Council of the Royal Society for the Protection of Birds, and the experienced ornithologists who advised the Government, all of whom considered that the Bill would have protected British birds more efficiently than the present Acts Mr. Crostliwaite states that "complaints are being received of the shooting of our song birds by Italians and other aliens resident in this country." This is a matter of interest which ought to be investigated, though it is difficult to see how Italians, granted they have obtained gun licences, could deplete the song birds of the country without trespassing on private property or breaking the ordinary laws of the land

IT is curious that in Great Britain, where comparatively little timber is grown, wooden poles are nearly always used for telegraph and electric power lines In France, Germany, and other countries where forests abound, armoured concrete poles are now becoming the rule The advantages of reinforced concrete over wood poles are that they are neater in appearance, last longer, and want little attention. Perhaps one of the reasons why there are so many wooden poles in Great Britain is that timber has been expensive for many years and it is advantageous to creosote it thoroughly so as to increase its life. Wellshaped poles also are only used. In a paper by T. Rich, published in the *Electrical Review* for Sept. 23, examples are given of the concrete poles used on the Continent. One reason which may have had weight in changing from wooden poles is that abroad the timber for poles seems to have been selected norther for appearance nor durability, and little use seems to have been made of preserving processes. In connexion with power transmission lines, the periodical painting of steel lattice masts seems to be a costly item. In France, since the War, there seems to have been continuous progress in the use of concrete supports, for distribution lines and poles of this type are seen in almost every part of the country. The poles are made on the ground in the open air and are carried to their destination by lorries. Many of the electric lighting companies have the right to put up lines along the roads at a small annual fee for each pole. Concrete posts have now been in use for several years. Owing to our climate we think that they might now in many instances be used advantageously in Britain.

The September issue of The Scientific Monthly mentions a remedy devised by Dr. James Couch, U.S. Department of Agriculture, for the irritation and eruption caused by poison ivy, which might be useful against other plant irritants such as Primula obconica It consists in the free application by swabbing of a 5 per cent. solution of potassium permanganate. The resulting brown staining of the skin may be removed slowly by soap and water or quickly by the application of a 1 per cent. solution of sodium bisulphite. As a preventive of plant rashes, Dr. James M'Nair recommends the application of a lotion consisting of a 5 per cent solution of ferric chloride in a mixture of equal parts of water and glycerin. It is washed on all exposed parts and allowed to dry.

Personal exercise of the arts and crafts at home in preference to the mechanical output of the factory is to be welcomed with every sign of ardour. Therefore a hearty greeting is due to books which may aid teachers in making the young idea shoot University of London Press is issuing a Handiciaft Series (1s 6d per volume) prepared by Mr. Frederick J. Glass, whom we also know as the author of the more ambitious work upon "Drawing, Design, and Craftwork," now in its second edition. Mr Glass exhibits more than a trace of the talent of Walter Crane in his adaptation of ornament and in the style of its portrayal. It may be noted, that the diameter must, necessarily, pass through the centre (vide "Pewter Craft," p. 36), and that a circle measures more than three times its diameter in circumference (vide "Paper Craft," pp 49 and 51). In commending the general style of the text, we may yet express our agreement with the author's reiterated statement, that practice and observation are more educative than a textbook Without wishing to be unduly critical, we may, however, remark, that it is irritating to be told frequently that it is "needless to say" so-and-so, when obviously so-and-so follows we must offer cordial approval of the illuminating notes upon the use of colour

The personal friends and colleagues of the late Prof Adrian Stokes have decided to establish some form of permanent memorial in recognition of the man and his work. They feel that the endowment of medical research, through the establishment of a Stokes Research Fellowship or Studentship, which is at present under consideration by the Medical School of Guy's Hospital, is the only form of memorial that would have met with his own approval, and they are anxious that the memorial should be worthy of one who lived and died for the manifestation of scientific truth. The Dean of the Medical School, Guy's Hospital, London, S.E. 1, will gratefully acknowledge any contributions to the fund.

With the opening of the 1927–28 session, the Institute of Metals takes possession of its new head-quarters, which include an additional library and reading room, at 36 Victoria Street, London. S.W 1.

THE thirty-ninth Congress and Health Exhibition of the Royal Samtary Institute will be held at Plymouth on July 16-21, 1928, under the presidency of the Right Hon. The Viscount Astor.

In recognition of his valuable services to public health, Sir Ronald Ross, director-in-chief of the Ross Institute and Hospital for Tropical Diseases, has been awarded the Harben Gold Medal for the year 1928 of the Royal Institute of Public Health.

The Kaiser-Wilhelm Institute for Anthropology was inaugurated in Berlin-Dahlem on Sept. 15 by Herr von Harnack, the president of the Kaiser-

Wilhelm Gesellschaft Prof Eugen Fisher, the director of the new Institute, outlined the programme. In addition to the anthropological department, there are others devoted to heredity and eugenics

SIR WILLIAM BRAGG will deliver a lecture on "Crystallisation" at the opening meeting of the 1927–28 session of the Institution of Chemical Engineers. The meeting will be held in the Institution of Civil Engineers, Westiminster, on Friday, Oct 28, at 6 30 PM. There will be no charge for admission, but tickets (to admit two) can be obtained on application to the honorary secretary. Institution of Chemical Engineers, Abbey House. Westiminster

The Chemiker-Zeitung for Sept 14 contains a special 30-page supplement dealing with recent advances in three important branches of chemistry. These reports, which are very highly condensed, and contain copious references to original memoirs, will be found to contain valuable summaries of progress in the following subjects: the investigation of elements and their structure during the period 1923–26, by Prof. W. Herz: the petroleum industry in 1926, by Dr. R. Kissling, and industrial inorganic chemistry from 1924–26, by Dr. Bruno Waeser.

In order to provide for the more speedy publication of contributions to the Faraday Society, the Council has decided that future volumes of the Transactions shall be published in twelve monthly parts of about 48 pages each. The first part will appear on Jan 1, 1928, and will be followed by the others normally on the first of each month. In the case of those General Discussions the report of which extends over more than one part, two (or more) parts may for convenience be published simultaneously within one cover. The subscription to membership of the Society (including the receipt of the Transactions) will remain as before. The Transactions will still be available to non-members in the volume form or in parts as issued.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :-- A principal of the Aston Technical College-The Chief Education officer, Education Office, Margaret Street, Birmingham (Oct. 17). A head of the chemistry department of the Rutherford Technical College, Newcastle-upon-Tyne—The Director of Education, North imberland Road, Newcastle-upon-Tyne (Oct. 29). An assistant lecturer in water supply and sewerage in the University of Western Australia —The Agent-General for Western Australia, 115 Strand, W.C.2 (Nov. 1). A professor of organic chemistry, pure and applied, in the University of Sydney, New South Wales—The Agent-General for New South Wales, Australia House, Strand. W.C 2 (Nov. 9). A research officer at the Vetermary Laboratory of the Ministry of Agriculture and Fisheries at New Haw, Weybridge—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Nov. 30). A superintendent of weights and measures under the Sudan Government-The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, S.W.1.

#### Research Items.

PALEOLITHIC SITE AT ROCHETTES, DORDOGNE --In 1925, Mm Courtier and Emetaz gave an account at the Archæological Congress at Grenôble of the excavation of a rock-shelter at Rochettes, immediately to the south of that explored by Hauser, which revealed a series of stratifications extending from the Lower Mousterian to the Upper Aurignacian, entirely undisturbed. In the Bulletin de la Société d'Anthropologie de Paris, 7<sup>me</sup> série, t. 7. fasc. 4-5-6, the authors describe further investigations on the site which have produced evidence of importance on three points. First, on the transition from Mousterian to Aurignacian. The lowest stratum (No 6), of dark yellow sandy soil, contained implements including racloirs of La Quina type belonging to Early Mousterian. Above this was a stratum, also of a sandy soil, lighter in colour, with coups de poing, oblong racloirs, and bones of developed Mousterian type. Above, in the fourth stratum, characterised by hearths with carbonised bone, was an industry much less highly developed than that of the stratum below, with numerous flakes, which in character are comparable to the industry of the Early Aurignacian rock-shelter at Audi. That is, the fully developed Mousterian is here followed immediately by an undeveloped industry of an entirely different technique, which is to be regarded as Aurignacian The site, therefore, gives indubitable evidence of the sequence of one industry to the other. The second point upon which the excavation furnished evidence is the occurrence of red ochre on a Mousterian site; a piece of this material showing two grooves made by a flint implement was found in the lowest stratum, which is taken to indicate that this material, used by the Aurignacians as pigment, was also employed by the Mousterians, though for what purpose is not known In the fifth or upper Mousterian stratum was found a bear's tooth, grooved for suspension as an amulet. This also is unique in Mousterian culture, and must be added to the small number of objects of amuletic purpose belonging to this culture already known.

ANTS AND APHIDS.—Observations on the relations ('trophobiosis') between ants and aphids have been made by H. Eidmann near Munich (Biol. Zentralbl., Band 47, p. 537-556, 1927). Certain aphids overwinter in the nests of *Lasius niger*, and these ants appear to exercise a sort of control upon the time of the going out of the aphids from the nest on to the trees. The aphids are watched and guarded by special watcher ants-workers-which remain, as marking experiments have shown, the whole day near their protégés and return each day again to the same place So long as the nights remain cold the aphids are brought back again into the nests of the ants. In summer when the aphid colony is very large and the nights are warm, the search by the ants for the aphids takes place after nightfall. The ants avoid daylight as much as possible, but nevertheless a watcher remains behind the whole day, even in bright sunlight, near each herd of aphids. The amount of food brought into a large colony of Lasius niger by its workers in their crops may amount to a litre of aphid honey during the summer.

Growth of Salmon.—In a paper entitled "Some Aspects of the Growth of Salmon in River and Sea as observed from Scale Examination of Dee (Aberdeen) and Spey Salmon 1921 to 1923 inclusive" (Fisheries, Scolland, Salmon Fish. 1927, I. (March 1927)), Mr W. J. M. Menzies summarises such conclusions as are warrantable on condition, calculated lengths and

times of rapid and slow growth Examination of condition, as represented by the relationship of weight to cube of length, shows that summer fish are fatter than spring fish, and that condition improves with age and length. A study of the calculated lengths reveals the fact that it is a general rule that the subsequent growth and behaviour of the pair and smolt are determined by the first year's growth A poor first year parr makes poor growth throughout the river life; a good first year parr increases its advantage in the second year, and probably then migrates to the sea as Spey parr and smolts are slightly longer than Dee parr and smolts This dependence upon the first year's growth appears to be maintained also throughout the marine life The slow growth period extends to April, during which month rapid growth begins and reaches a maximum in August. A check during rapid growth occurs in many fish in June and July. With the accumulation of further material, the Scottish Fishery Board will be in a position to review the final distribution of the complete hatch of a single season in either Dee or Spey.

THE SIZE OF WHALES—The literature of whales and whaling has been much added to of late, and five of these recent works are made the subject of an interesting article by Mr. J. J. Bell in the July issue of *The Quarterly Review* While the greater part of the article is devoted to a review of "Pursuing the Whale " (Murray, 1926), a circumstantial account by Capt. John A. Cook of his whaling adventures, the chief scientific interest attaches to an incident m Mr. Bell's own experience. It has been very generally assumed that the Blue Whale (Balænoptera musculus (L.) = B. sibbaldii (Gray)) attams to much greater dimensions in the Antarctic than in the Arctic Ocean, and some naturalists tend to distinguish the southern form as a distinct race. Trustworthy data regarding the upper limit of this species in northern waters are therefore of value. Mr. Boll states that in northern Iceland he measured a specimen between perpendiculars and found it to have a total length of 86 feet. This measurement would place his example among the largest recorded from the Arctic On the other hand, he also mentions receiving "the trustworthy account of a Blue Whale killed in the Antarctic, which measured 110 feet," a record which, if really trustworthy, would tend to support the view that a greater size is there attained by this species. Perhaps, however, the true solution is that suggested by Sir Sidney Harmer (*Proc. Zool.*) Soc., p. 1089, 1923), namely, that Blue Whales of the largest size have become practically extinct in the north on account of the long-continued intense whaling in those waters.

BEACH VEGETATION IN THE PHILIPPINES—The classical work of Schimper on the beach vegetation of the Indo-Malayan region will always form the basis for any work of that kind done in this region—Schimper, however, does not discuss the ecological anatomy of the sandy beach species—Recent work by Raymond Kienholz (Proceedings of the American Philosophical Society, vol. 55, No. 5 (Supplement), 1926) is thus of interest because, apart from the distribution of the various species, the author has made a detailed study of the anatomy of a number of species in relation to the particular conditions of this beach environment. The beach is divided into three physiographic areas, each with its characteristic flora: (1) Sandy beach; (2) rocky headland, and (3) muddy flats, of which only the first two are considered in the present paper.

The sandy beach is characterised by creeping herbaceous forms, such as Spinifer littoreus, and Ipomaa pes-capiæ, with a shrub-tree zone on the upper beach composed chiefly of Scavola frutescens, Tournefortui argentea, Pandanus spp. and various trees The flora of the rocky headland is derived partly from the sandy beach, partly from the interior forests. In both habitats evaporation is high, wind movement strong and steady. Intense sunlight, salt spray, and rapid drying out of the sand, together with the factors first mentioned, produce a severe environment, particularly as regards the water relations of the plants. The author considers that these severe environmental conditions have affected the habit and especially the leaf structures of the species Leaves of the twentytwo species examined exhibit many xerophytic structures—leaves more than 350 microns in thickness large quantities of water storage tissue, sunken Very detailed measurestomata, and thick cuticle ments are given of the various structures, which are illustrated by seven plates.

STORAGE AND TRANSPORTATION DISEASES OF VEGETABLES —In No 81 of the Technical Bulletin of the Agriculture Experiment Station, Michigan State College, Ray Nelson records some work he has carried on along lines similar to those followed by Franklin Kidd, Cyril West, and M. N. Kidd for the Department of Scientific and Industrial Research (see Nature, vol. 119, June 4, p. 830). These latter investigators found that by controlling the storage atmosphere of living fruit through a reduction in the percentage of oxygen and an increase in the carbon dioxide, the storage life of the fruit could be lengthened present author now traces certain non-parasitic diseases, including black lear speck of Cruciters, red meast of lettuce and cabbage, and surface pitting of potato tubers, to madequate supplies of oxygen in the storage chambers, or to temperatures which prevent the utilisation of the oxygen present. He has been able to reproduce some of those diseases under controlled laboratory conditions, and comes to the conclusion that both the factors of air composition and temperature are important in causation. In some of his experiments the amount of oxygen in the atmosphere fell as low as 25 and 1.0 per cent He suggests that the ultimate cause of those diseases is the liberation or accumulation in certain cells of some toxic substance resulting from the interaction of a hydrolytic enzyme and a glucoside, due to a deficiency of oxygen, one of the results of this interaction being an oxidation process causing the pigmentation characteristic of many of those break-down diseases. As a control measure proper aeration of storage chambers is recommended. On the other hand, the Cambridge investigators found that a regulated atmosphere containing a constant 10 per cent. of oxygen and a corresponding increase in carbon dioxide gave the best results As the research stands at present, there seems to be an optimum concentration of oxygen which slows up respiration sufficiently to give increased longevity to storage fruit and vegetables, but, if decreased, it may give rise to the various pathological symptoms incidental on suboxidation which the author describes.

The Rainfall of Australia.—The rain map of Australia for 1926, published by the Commonwealth Government, contains, as usual, maps showing the monthly tall and departures from the normal. It is based on the records of some 1300 stations. During the year, as in the previous four years, less than one-quarter of the continent had rainfall above the average. In the south-west of Western Australia the fall was the greatest on record. There were also good rains in

the northern and central areas of New South Wales and in south-eastern Australia. But some parts of the continent experienced serious drought. In Queensland the drought which began in 1925 became more pronounced and had disastrous results, causing great loss of sheep, a failure of cereals, and a much diminished output of sugar. In South Australia the rain was below the average, but on the whole there was no serious shortage. In New South Wales, Victoria and Tasinania the rainfall conditions were generally favourable and local deficiencies were only slight.

PTOLEMY'S TORTOISE MARSHES —Much speculation has ranged round the identity of Ptolemy's Tortoise marshes (Chelonitides paludes), which he placed on his river Gir in lat. 20° long 49°. Various authorities have identified the marshes with Lake Melghii in southern Algeria. Lake Fittii in the Wadai region, or the salt lake of Merga in lat 19° 3′, long 26° 19′. In a paper in the Geographical Journal for September, on the problems of the Libyan desert, Dr. J. Ball discusses these identifications. He visited Lake Merga, and cannot reconcile it with Ptolemy's description of the Tortoise marshes In its place he suggests the Kufra oasis Correcting Ptolemy's positions in terms of his known errors. Dr Ball finds that Kutra is in close agreement with the Tortoise marshes Further, he points out that the Kufra is an extensive tract of low ground with many lakes and salt marshes and has distinctly the form of a valley. This might easily have suggested a series of marshes formed by a river coming tiom the south-west. Ptolemy might have mistakenly interred that the river reached the Mediterranean.

FIRE RESISTANT CONSTRUCTION.—Special Report No 8 of the Building Research Section of the Department of Scientific and Industrial Research (London: H.M. Stationery Office, place 1s. 6d net.), deals with the effect of high temperatures on building materials generally, and describes experiments carried out in the endeavour to elucidate and then to improve the fire-resisting properties of concrete. It is shown that by the addition of a pozzolanic material to Portland cement, a very considerable absorption of the line (set free on hydration of the cement) can be brought about. The presence of the lime is shown to be the most serious factor in the deterioration of cement under fire The work described has been carried out over a period of two years, and the results are, therefore, considered to represent actual conditions fairly well. A report will be issued when the material has been under observation for five years. The report is well illustrated and provided with a bibliography, and it represents a very valuable addition to our knowledge of building materials.

THE GRAVITATIONAL CONSTANT -A preliminary notice of a new determination of this quantity at the U.S. Bureau of Standards has been published by P. R. Heyl in the August number of the *Proceedings* of the National Academy of Sciences. The method employed was one in which a torsion balance is used dynamically. The attracting masses were steel cylinders, each weighing 66 kg., and the oscillating system consisted of two 50 gm. platinum balls on the ends of a light rod of aluminium, which was suspended by a thin tungsten filament wire a metre long; elaborate precautions were taken to ensure that the metal was homogeneous. The time of oscillation was 29 minutes when the gravitating bodies were as near as possible, and rose to 34.5 minutes when they were separated. The five values of G obtained in 1926 differ amongst themselves by less than one part in a thousand, and yield a mean value of  $6.664 \times 10^{-8}$ .

# The International Congress of Physics.

DURING the week commencing on Sept 11, a meeting of exceptional interest was held at Como in Italy, in commemoration of the first centenary of the death of Volta. It is probable that no previous congress has ever brought together so representative a gathering of physicists, for, with very few exceptions, the leading authorities in all branches of the subject attended the meeting and gave short addresses on developments in their own fields Fourteen countries were represented by about sixty guests who were invited to attend the congress; these included amongst their number eleven Nobel laureates The meeting will surely be remembered as a historical

The programme was divided into five general sections, one for every day.

(1) Researches into the structure of matter.

(2) Electricity and its applications.

(3) Electrical theory

(4) Physical optics

(5) Theories of the structure of matter and of

On the sixth day, in the lecture-room of Volta at the University of Pavia, a résumé of the work which had been accomplished and of the problems discussed was presented by Prof. Lorentz representing the theoretical physicists and by Prof. Majorana re-

presenting the experimental physicists.

The scientific meetings at Como were followed by a visit to Rome. The members of the Congress were received by the Italian Premier, Signor Mussolini, who expressed his appreciation of the work which had been accomplished. Senator Marconi. who delivered an address in the Capitol on Volta's life and work, expressed the feelings of all who attended the conference when he congratulated the president, Prof Majorana, and secretary of the Congress. Prof. Pontremoli, on the way in which the meeting was organised and conducted.

The following brief notes will indicate the trend of

the discussions which took place:

# RESEARCHES INTO THE STRUCTURE OF MATTER.

The meeting was opened with a lecture by Sir Ernest Rutherford, on the structure of radioactive atoms and the origin of a-particles. Sir Ernest proposed a new theory which, introducing neutral particles around the nucleus, gave an explanation of many experimental facts. A general discussion followed, conducted principally by Prof. Lorentz. Prof. J. Franck of Gottingen gave afterwards a very interesting account of "Band Spectra and Chemical Phenomena," in which he put forward a new optical method of determining the energy of dissociation of normal or excited molecules.

Dr. F. W. Aston described his latest results with his improved mass spectrograph and the conception of the structure of nuclei to which they led. In his paper he referred to the theories of Sir Ernest Rutherford described above. Dr. Aston also announced the discovery of some new isotopes. Prof. Gerlach spoke about magnetic susceptibilities of gases; he developed the theory of the experiment of Stern and Gerlach, and announced that experiments made on susceptibilities of gases show conclusively that no quantisation of direction is present in diamagnetic gases. Prof. Cabren described the magnetic properties of the palladium and platinum groups and their significance in the theory of paramagnetism. Prof. Stern described a new method for studying the electrical and magnetic deflexion of molecular rays, and gave some account of experiments on the reflexion of hydrogen molecules at a highly polished plane surface Prot H. D. M. Bose presented some investigations on paramagnetism Prof W. L Biagg gave a highly appreciated account of the diffraction of electromagnetic waves by crystals, and Prof Smekal opened an interesting discussion on the structure of actual crystals. Prof. Langmuir described some very recent observations on the electrical discharge in gases at low pressure, and directed attention to important questions in this field. The Due de Broglie spoke on the absorption by matter of Rontgen radiation, and Prof Compton dealt with the action of radiations upon electrons.

#### ELECTRICITY AND ITS APPLICATIONS.

The discussion was opened with reports by Prof. Kennelly on the normal attenuation in electrical nets, by Prof. K. W. Wagner on electrical filters and reiterative conductors, by Prof. Boucherot on the utilisation of the cold water of the bottom of the ocean. Prof. Janet spoke on the construction of electrical machines, and Prof. Cotton described the great magnet now in construction at the laboratory of Bellevue, France, which is designed to give strong and extended magnetic fields and will require 100 kv. for its excitation. Prof. Tolman described his experiments on electrical effects due to mechanical movements of matter. Prof. Majorana demonstrated with experiments his method of transmitting speech by ultra-violet light, Prof. Wood gave an extremely interesting report on biological and physical effects produced by ultrasonic vibrations obtained with piezoelectric oscillators. The oscillator works at 500,000 periods and very curious effects are observed In oil a very marked pressure of radiation is detected; a glass wire acted on by these vibrations gives high calorific effects, frogs and fishes are killed; the action of these ultrasonic vibrations were illustrated by means of slides, and many questions were put to Prof Wood, whose work opens a very wide field for research. Finally, Prof. Brillouin gave an account of a problem of atmospheric electricity, and Prof. Alcobé presented a historical note on an electrical telegraph preceding the discovery of the cell.

#### ELECTRICAL THEORY.

Prof. Lorentz, who received a great ovation, opened the discussion with a paper on some difficulties connected with the problem of rotating electrons. Prof. Planck discussed the difference of potential in diluted solutions. Prof Corbino the theory of the voltaic cell recently proposed by him, and Prof. Hall the Volta-effect. Afterwards, Dr. Frenkel gave some very interesting views on the electronic theory of metals, and Prof Gruneisen discussed the more recent experiments on thermal and electrical conductivities of metals. The theory of the Voltaeffect and triboelectricity was also discussed in the report of Prof. Perucca Prof. Ehrenhaft spoke on the physics of submicroscope matter, Prof. Lasareff on an electrical theory of vision, Prof. Amaduzzi on a peculiar example of photoelectricity.

#### PHYSICAL OPTICS.

Prof. Millikan reported on cosmic rays: his communication was followed with deep interest and gave rise to discussion by Sir Ernest Rutherford, Prof. McLennan, and others. Prof. La Rosa reported afterwards on the ballistic theory of light; his observations were criticised in a following lecture by Prof. Giorgi, who proposed also some new experiments as crucial tests between the Ritz-, Einstein, and Fresnel-Maxwell-Lorentz theories

Prof. McLennan spoke on the spectrum of the aurora and our knowledge of the high atmosphere. Prof Richardson gave an account of his work on the molecular hydrogen spectrum. Prof Paschen dealt with some new methods of spectroscopic work. Prof. Duane with the character of the general X-radiation, Prof. Saha with the explanation of complex spectra as interpreted by undulatory mechanics Prof. Zeenan gave afterwards a very bulliant and complete report on the emission of radiation in a magnetic field, and illustrated his account with many very interesting slides Prof. Americ closed the meeting with a report on solar radiation.

THE STRUCTURE OF MATTER AND RADIATION.

Prof. Sommerfeld dealt with the theory of metallic conduction and the Volta-effect interpreted by Fermi's statistics, Prof. Levi-Cività proposed a new theorem on adiabatic invariants, Prof. Debye gave an account of the recent work done by himself and his school on dielectrics and the dipole theory, Prof. v. Laue spoke

on the influence of temperature on X-rays interference, Prof Eddington on electrical conditions in stars, Profs Straneo and Gianfranceschi on quantum theory

Prof. Bohr gave a very clear and detailed report on the actual state of quantum theories—he illustrated the points of agreement and of discordance between the different theories and between theory and experiment, and closed his important speech with some philosophical observations on the atomic world. A general discussion followed, conducted by Profs—Born, Krainers, Heisenberg, Fermi, and Pauli, in which the actual situation of this branch of science was reviewed.

The Congress left a very deep impression on all who were privileged to be present, since it provided so complete a review of the more recent developments in all branches of physical science. The discussions were presided over by Prof Majorana (president), and by Sir Ernest Rutherford. Profs. Lorentz. Millikan, and Cotton (vice-presidents). At the conclusion, a resolution was passed proposing that the committee which organised this Congress should be made permanent and endeavour to arrange similar meetings in future years.

# Annual Visitation of the Rothamsted Experimental Station.

AT the invitation of Lord Clinton, chairman of the Lawes Agricultural Trust, a number of visitors inspected the Rothamsted station and laboratories at Harpenden on Sept 29.

Lord Clinton, in welcoming the visitors, briefly outlined the purpose of the station, and its special opportunities in the present world-wide agricultural depression. The remedy of reduced production, he said, is a cry of despair, and the sounder way of meeting the situation is to intensify the level of production.

at a relatively reduced cost.

Sir John Russell, director, reviewed in detail the recent activities of the station. The new glass houses erected with the help of a generous donation from the International Education Board, Rockefeller Foundation, are in use for the study of plant diseases and the preliminary tests of new fertilisers and accessory materials. The periodical conferences held at the station are proving very successful; they are of two kinds: (a) practical, when some specific agricultural problem is discussed by farmers and the station staff, and (b) expert or technical, in which overseas and foreign workers participate, when the position of some fundamental inquiry, as for example soil reaction, is discussed. These conferences not only serve to disseminate widely the latest developments, but are also of great help to the station in drawing up a well-balanced programme of work.

The subject of crop production and improvement naturally bulks largely in the programme of the station. The improved method of seed inoculation for lucerne is enabling the crop to be grown outside the hitherto restricted south-east area of England, and the demand from farmers for cultures is still increasing Progress has also been made in the study and control of the elusive factor of quality in certain crops. Prominent among these are sugar-beet, potatoes, and malting barley, in which respectively the sugar content, the behaviour on cooking, and the character of the malt are as important as the actual yield. At least three-fourths of the malting barley used is home grown, but owing to the influence of introgen content on the malting quality, farmers are loth to use nitrogenous manures to increase the yield.

Co-operative experiments with the Institute of Brewing have shown, in general, that moderate top dressing of nitrogenous tertilisers can be safely used, and the problem is now being pushed a stage further, by biochemical studies of the grain.

Thanks to mathematical study of the statistical requirements of field plot experiments, it has been possible to use greatly improved systems of replicating and randomising the plots, with a concomitant increase in accuracy of the data of yield. At the same time, by keeping the plots under close examination during the growing season valuable physiological and ecological information is being secured, both on the relation of soil and climatic factors to plant growth, and on the connexion between the life-history of the plant and its final yield.

In the field, the comparative effects of alternative systems of cultivation are being directly investigated on a variety of crops. Extended use is being made of the new dynamometer in studying the production by implements of a good soil tilth, and the field observations are being closely followed by laboratory studies of the physical and physico-chemical soil

properties concerned.

Progress has been made in producing synthetic farmyard manure, and the process, developed originally in the Rothamsted laboratories, is now in use all over the world. It has been found of great value in the Empire, particularly in regions where surplus straw, etc, has hitherto been wastefully burnt. In connexion with the purification of the effluent from sugar-beet factories, the earlier Rothamsted work on sewage purification in a filter bed is proving useful.

The new glass houses have enabled the station to add the study of tropical and subtropical plant diseases to its activities. The general endeavour in this work is to aim at preventive rather than curative measures. Nevertheless, the necessity for trustworthy insecticides and fungicides to deal with heavy intestations of disease or pests will remain almost indefinitely, and therefore quantitative investigations on the relation of chemical composition to toxicity, especially of insecticides, are being continued.

Sir Isaac Pilman and Sons, Ltd.—Introduction to Textiles, A. E. Lewis.

# University and Educational Intelligence.

The Sir John Cass Technical Institute of Aldgate, London, offers in its prospectus for 1927–28 a wide range of choice of subjects. Among the more specialised courses are those in gas manufacture and analysis, brewing and malting, and petroleum technology. There is an important department of metallurgy in which students are prepared for the University of London degree of B.Sc. (Engineering) in metallurgy. There are also a department of arts and crafts (including silversmithing, jewelry, and engraving), trade classes, and a nautical school. The new session will be opened on Oct. 10, when Sir William Beveridge will give an address.

THE International Institute of Intellectual Co-operation issues quarterly a Bulletin of Scientific Relations. The issue of August last contains notices of recent and forthcoming international congresses, newly constituted scientific organisations, activities of the scientific relations branch of the Institute, and several special articles and reviews. A description is given of the new "Fondation Edmond de Rothschild," the object of which is to establish at Paris an institute of biology for the investigation of the physicochemical basis of life For this purpose a sum of thirty million francs has been placed at the disposal of a council of twenty-four, comprising delegates nominated by learned societies and members co-opted by the already existent Rothschild foundation for physics and chemistry. The founder holds that of late years the study of micro-organisms has tended to distract the attention of biologists from pursuing the lines of research in physico-chemical reactions associated with the name of Claude Bernard. The new institute will afford facilities for the resumption of research on those lines.

The place of university extension work in State universities in the United States is thus defined in the 1927 "Catalogue" of the University of Colorado . the University's first duty is to teach the students upon its campus, the second to foster and develop the spirit of research on the part of the members of its faculties, the third to render to the State at large such public service as may lie within its power. This third function is exercised through the extension division which is the official representative of the university to its constituents, the whole citizenship of the State. The work of the Colorado University extension division is organised in two departments, those of instruction and of public service. The former has bureaux of correspondence instruction, of class instruction and of visual instruction (chiefly for schools and churches), home-reading courses, and lecture courses. The 'class instruction' is for teachers, club members, business men, industrial workers, and any other group having a common It is comparable with the university tutorial classes of England. The department of public service has bureaux of business and government research, community organisation, library extension, and research and extension in journalism, and it conducts high school visitations and helps to operate a high school debating league. The business research activities include the making of industrial surveys and retail cost surveys, and the conduct of research on various problems connected with public utilities. Community organisation' stands for services in connexion with such matters as public health, child welfare, recreation, and juvenile delinquency. The University Library serves as a reference library for the people of the entire State The journalism bureau is operated jointly by the Extension Division and the celitorial association of the newspapers of Colorado and serves as a common clearing house of information for them.

# Calendar of Discovery and Invention.

October o. 1837.—Under this date. Caroline Fox records a conversation with Davies Gilbert, who gave us interesting accounts of his interviews with George IV. William IV. and the Queen; the two former he visited in right of his Royal Society's Presidentship to get their signatures. To George IV. he went and requested that he would confirm the patent as his royal predecessors had done, and pointed out to him several of their signatures. Would you show me Evelyn's, said the King—I have lately been reading his memoirs with great interest.' Davies Gilbert found and showed it, when the King remarked. 'He was the founder of the Royal Society' Gilbert said it was His Majesty Charles II who gave the first charter. Very true, replied the King, but that was only ex officio, any man who had happened to be in his situation would have done that; but Evelyn was the real founder, you may depend upon it

October 9, 1856—A few days before the first Atlantic Telegraph Company was registered, Bright and Whitehouse, at the offices of the Magnetic Company in Old Broad Street, London, on Oct 9, 1856, showed Morse that signals could be sent at the rate of 272 per minute through 2000 miles of the Company's wire between London and Manchester.

October 10, 1846 -Within seventeen days of the discovery of Neptune by Galle, the Liverpool brewer Lassell, on Oct 10, 1846, with the aid of a fine twofoot reflector, discovered its single satellite. The study of this satellite has enabled the mass of Neptune to be calculated with great exactness

October 11, 1867.—The modern typewriter had its birth in Milwaukee It was the result of the joint labours of Sholes, a collector of customs, editor and printer, Soule, a farmer and printer, and Glidden, a farmer and inventor. Their machine was patented on Oct. 11, 1867, and after many improvements its manufacture was taken up by the Remington firm of gun-makers.

October 12, 1788. - One of the earliest recorded steamboat trials was made in America on Oct. 12, 1788, when one of Fitch's boats fitted with an engine having a cylinder 12 in. in diameter carried thirty passengers from Philadelphia to Burlington, a distance of about 20 miles, in 3 hours 10 minutes. Ten of the passengers afterwards signed a certificate declaring "We, whose names are hereunto subscribed, do certify that we have been in John Fitch's steamboat of 60 ft. in length in the river Delaware, when the said boat was propelled through the water with a considerable degree of velocity regularly and without any manual labour, by the force of steam, and we are clearly of opinion that the rivers of America may be navigated by the means of steamboats, and that the present boat would be very useful on the western waters.'

October 13, 1877.—The first experiment in street lighting by electricity in France was made on Oct. 13, 1877, when the Place de l'Opera in Paris was lighted by a series of Jablochkoff candles.' Jablochkoff was a Russian electrician who died in poverty in 1894.

October 14, 1788 -Patrick Miller's steamboat experiments in Scotland were contemporary with those of Rumsey and Fitch in America; and it was on Oct. 14, 1788, that a trial was made, on Dalswinton Loch, with one of Miller's double-hulled boats fitted with a steam engine by Symington. The enterprise being abandoned, the engine was removed to Miller's library and sixty-five years later was saved from the scrap heap by Bennet Woodcroft. It is now in the Science Museun, South Kensington. E. C. S.

# Diary of Societies.

FRIDAY, OCTOBER 7.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Discussion on The Meeting of the International Union of Geodesy and Geophysics at Prague, 1927, September 3-10. Chairman Sir Gerald Lenox Conyngham. Speakers Sir Henry Lyons, Prof. Turner, Prof Chapman, Prof. Proudman, Dr. Crichton Mitchell, Mr. Lempfert, Mr. Mattheway 2014 Chem. Matthews, and others.

#### SATURDAY, OCTOBER 8.

SAIGNDAY, OCTOBER 6.

BIOCHEMICAL SOCIETY (IN BIOChemical Laboratory, Cambridge), at 3.—
Dr. S B Schryser and K. V. Thimann The Scission of Gelatin into Constituent Proteins.—G. S. Haynes and C. G. L. Wolf The Interferometer Method for the Diagnosis of Pregnancy and Malignant Growths.—I. Smedley MacLean. The Isolation of a Second Sterol from Yeast Fat.—T S. Hele. On the Origin of Ethereal Sulphates —J. R. Marrack and L. F. Hewitt The Osmotic Plessure of Iso electric Egg Albumm —L. F. Hewitt: Adsorption of Phthalein Dyes by Proteins.—M. Stephenson. On a Cell-free Dehydrogenase Obtained from Bacteria.

Bacteria.

Hull Association of Engineers (at Technical College, Hull), at 7 15.

J. Shepherd: Three Years' Engineering in Mesopotamia

#### MONDAY, OCTOBER 10.

ROYAL SOCIETY OF MEDICINE (War Section), at 5 —Surg. Vice-Admiral A. Gaskell: Professional Opportunities of the Service Medical Officer (Presidential Address)

BRITISE PRYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6 — Miss E. G. Hume: Disability in Reading. Institution of Automobile Engineers (Bristol Centre) (at Merchant Venturers' Technical College), at 6 45.—Major R. G. Beaumont: The Influence of the Automobile User upon the Automobile Engineer (Presidential Address). (Presidential Address).

(Presidential Address).

INSTITUTE OF METALS (Scottish Local Section) (at Institution of Engineers and Shipbuilders in Scotland, 39 Elmbank Crescent, Glasgow), at 730—S. E. Flack: Chairman's Address.

INSTITUTE OF BREWING (London Section) (at Engineers' Club, Coventry Street, W 1).—Discussion on Season's (1926) Malts.

MEDICAL SOCIETY OF LONDON.—H. W. Carson: Surgery in the Early Days of the Medical Society of London (Presidential Address)

#### TUESDAY, OCTOBER 11.

ROYAL SOCIETY OF MEDICINE (Therapeutics Section), at 5—Dr. J A Gunn. Pharmacological Syndromes (Presidential Address)
INSTITUTION OF PETBOLEUM TECHNOLOGISTS (at Royal Society of Arts), at 530.

AUGUST OF MARINE ENGINEERS, at 6 80.—A F C. Tinipson: A New Form of Insulating Material for High Temperatures.
INSTITUTION OF HEATING AND VENTILATING EXONEERS (at Caxton Hall, Westminster), at 7.—Dr. J S Owens: Atmospheric Pollution

No. 3023, Vol. 1201

QUERETT MICROSCOPICAL CLUB, at 7 30 -Dr W B Briefley The Micro-flora of the Soil

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES (at Royal Society of Arts), at \$15-Dr J Rickman and Dr H. G Baynes The Standpoints of Freud and Jung

#### WEDNESDAY, OCTOBER 12

Society for the Study of Inderitt (at Medical Society of London), at 4-Prof W E Dixon The Tobacco Habit (Norman Ken Memonal

Lecture)
INSTITUTE OF METALS (Swansea Local Section) (at Thomas' Cafe, High Street, Swansea), at 7—Capt L Taveiner Chairman's Addiess Folk-Lore Society (at Wellcome Historical Medical Museum), at 8 OIL AND COLOUR CREMISIS' ASSOCIATION (at Royal Society of Arts), at 8—Dr C Beavis, Dr L C Martin, Dr S G Barker, Mrs F E Loubond, J Guild, R S Horsfall, and others Discussion on Colour Standardisation and Testing in the Paint and Colour Industry Institution of the Rubber Industry (London and District Section) (at Engineers' Club, Coventry Street, W 1)—Dr. O. de Vries. Coagulation, Structure, and Plasticity of Crude Rubber.

#### THURSDAY, OCTOBER 13

ROYAL PHOTOGRAPHIC SOCIETY OF GRFAT BRITAIN (Colour Group), at 7.

—J C Warburg The Colour Slides of Lantein Plate Size, included in the Annual Exhibition, to be shown on the Screen
INSTITUTE OF METALS (London Local Section) (at Society of Motor Manufacturers and Tradeis, Ltd., 83 Pall Mall, S.W.1), at 7.30—A. H. Mundey Works' Economics (Chairman's Address)
INSTITUTION OF THE RUBBLE INDUSTRY (Birmingham and District Section) (at Grand Hotel, Birmingham)—A. E. Hemsworth Selling

#### FRIDAY, OCTOBER 14

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 -Sir Aithur Keith Results of Recent Researches into the Reproduction and Growth of

Hone
JUNIOR INSTITUTION OF ENGINEERS, at 7 30.—F A SIMPISON. Problems
created by the Rapid Development of the Motor Car Industry.
INSTITUTE OF METALS (Sheffield Local Section) (in Non-Ferrous Section
of the Applied Science Dept, The University, Sheffield), at 7.30—
J H G. Monypenny Science and Industry (Chairman's Address)
Society of Chemical Industry (Chairman's Address)
Society of Chemical Industry (Chairman's Address)
Society Development of Spray Development of Development of Spray Development of 
Spray Drying

SATURDAY, OCTOBER 15

Physiological Society (at Guy's Hospital), at 3 30

#### PUBLIC LECTURES.

SATURDAY, OCTOBER 8

HORNIMAN MUSEUM (Forest Hill), at 330—Prof. J R Ainsworth Davis: The Romance of the Spice Islands.

#### MONDAY, OCTOBER 10

UNIVERSITY COLLEGE, at 5 -J A Wilks The Library of University College -Prof G Dawes Hicks. A Century of Philosophy at University College -R J Lythgoe Vision (Succeeding Lectures on October 12, 17, 19, 24, and 25)

#### TUESDAY, OCTOBER 11

University College, at 3 - Prof E A. Gardner The Study of Greek Sculpture

#### WEDNESDAY, OCTOBER 12.

KING'S COLLEGE, at 5 30 .- Prof J Dover Wilson: The Nation and its Schools

LONDON SCHOOL OF ECONOMICS, at 6 —L. S. King. Office Machinery. Demonstration of the Teletype.

#### THURSDAY, OCTOBER 13

University College, at 5 15 -Dr. T. G Pinches: New and Noteworthy Assyrian Texts.

# FRIDAY, OCTOBER 14.1

UNIVERSITY COLLEGE, at 5 - Dr Phyllis M Kerridge . Hydrogen Ion Concentration. (Succeeding Lectures on October 21 and 28)

### SATURDAY, OCTOBER 15

Horniman Museum (Forest Hill), at 3 30 -Miss M A Murray Egyptian Temples.

#### CONGRESSES.

OCTOBER 8 TO 11

INTERNATIONAL CONGRESS OF HYDROLOGY, CLIMATOLOGY, AND GEOLOGY (at Lyons).

OCTOBER 11 TO 15.

FRENCH CONGRESS OF MEDICINE (at Paris)

OCTOBER 16 TO 22.

CONGRESS OF INDUSTRIAL CHEMISTRY (at Paris).

OCTOBER 18 TO 23.

JORNADAS MÉDICAS DE MADRID (at Madrid).

# SATURDAY, OCTOBER 15, 1927.

# Imperial Agricultural Research.

T is distinctly unfortunate that the first seven plenary sessions of the Imperial Agricultural Research Conference were held during the week in which two political parties held their annual conferences. The subject matter under discussion at the research conference is of the greatest significance to an Empire in which the foremost industry is agriculture and the future of which depends wholly upon the progressive realisation of the vast potential resources of the lands which it embraces. Nothing has been left undone by the Empire Marketing Board and the Ministry of Agriculture to emphasise these two points reports, memoranda, and pamphlets which they have prepared and distribated to the delegates present for their information and guidance in discussing the various items on the agenda are calculated to interest a wide public, and would undoubtedly have been extensively used by the Press for this purpose had the meetings to which they refer been held a week earlier 
It can scarcely be expected, however, that the Press will give undue prominence to a conference dealing with such impersonal and serious questions as those relating to the influence of scientific research upon our economic position, unless they are dealt with in a brilliantly illuminating and arresting manner and by speakers who have attained a position in popular esteem which rivals that held by the leaders of the Conservative Party and the Labour Party respectively.

The items on the agenda were so arranged that the plenary sessions during the opening week were devoted to the consideration of administrative questions The task of considering the agricultural problems confronting the various parts of the Empire, for the solution of which the aid of science must be invoked, has been delegated to groups of specialists. Now it cannot be suggested seriously that any of the so-called technical questions which have been delegated for the consideration and report of specialist commissions, questions affecting veterinary science, soils and fertilisers, plant pathology, the preservation and transport of food and raw materials, animal and plant genetics, agricultural economics and dairying, are without interest for any of the delegates present at the Conference. Time spent on the discussion of the problems related to these various branches of agricultural research would have been exceedingly well spent The delegates would have been able to grasp the magnitude of the responsibilities of the agricultural services, they would have been able to envisage their problems as a whole and the inter-relations of the work already being carried out in various constituent parts of the Empire, and to survey the possibilities of co-operation in connexion with the researches already in progress and those others which the Conference might decide were imperatively needed.

However, it was pre-ordained that the Conference should give first consideration to administrative questions relating to staffs and institutions. The discussions which arose out of them at the plenary sessions are certainly illuminating. . In connexion with man-power, it was alleged that there is a serious shortage of suitable candidates for most branches of scientific services supported by Governments, a shortage which is being accentuated by the growing demand for specialist officers made by the non-self-governing dependencies. The Research Sub-Committee of the Imperial Conference attributed this shortage to the wholly inadequate appreciation of the importance and value of scientific research on the part of the public, of the Press, and even of Governments themselves: to the uncertainty in the minds of students embarking on a university course as to the career offered by agricultural research: to the increasing demand by private employers for men with a university training in science: and to the lack of knowledge shown by educational institutions and parents of the careers available overseas in the various branches of science and their special attractions. The shortage of candidates is particularly acute in the services—other than medical—for which a training in the biological sciences is a requirement.

The only satisfactory and permanent remedy for this state of affairs, suggested Lord Lovat, Parliamentary Secretary of State for the Dominions, is to make the Agricultural Research Services in pay, status, career, and rewards the equal of other Government services carrying equal duties and responsibilities. It is folly to expect that the best men from the universities will be attracted to agricultural science while there are so few definite and certain prizes at the top. High initial pay is an insufficient inducement. Practically every subsequent speaker endorsed these views, which will obviously commend themselves to every scientific worker in the Empire.

These are the views which have been advanced from time to time in our columns. Generally speaking, the flow of entrants to a career is regulated by its attractiveness, and not the least attractive aspect of a career is its estimation in the public

This esteem must be more than recognition of the money value of those officers who enter specialist services, it should include a proper understanding of their creative outlook. Nothing has done more harm to scientific workers than the popular acceptance of the theory the those who have achieved eminence in a particular field of science have become so specialised in their interests and so biased as to render them unfit for positions of administrative responsibility. Too early specialisation in a student's career would, it is true, tend to produce an undesirable narrowing of outlook, but provided specialisation is left to the post-graduate stage of a student's educational career, there could be no better preliminary training for future administrators than that provided by a liberal and general course in science. This fact has been recognised by certain provincial governments in India. They have been recruiting their Indian administrative staffs from the scientific institutions, particularly the colleges of agriculture in their provinces, and have found this method thoroughly satisfactory.

It is imperative that any general science course in the schools should include general biology as a subject and should not be confined, as it is in most schools in Great Britain, to physical and chemical science. The interest which is stimulated in a subject at school has a direct bearing upon the course of study undertaken at a university. Moreover, as Sir Daniel Hall rightly observed, biology should be taught in the schools not only because the Empire will have to make greater and greater demands for trained investigators in the field of biology, but also because no man can properly be regarded as well-educated who does not fundamentally understand how a plant grows and how an animal lives and has its being. If, moreover, as Sir John Farmer pointed out, an interest in biology were stimulated in the schools, it would not be taken up as a 'soft-option' at the universities mainly by those students who were conscious of their deficiencies in physics and chemistry.

The suggestion that the shortage of biological students at the universities is due to the lack of endowments for biological study was discounted by Major Walter Elliott. He emphasised the fact that there is no shortage of candidates for the medical schools, for the obvious reason that parents are satisfied that medicine provides a satisfactory career for their sons and daughters. To the proposition that scholarships should be provided for public and other secondary schoolboys to enable them to take up agricultural science at the uni-

reprisity under the condition that they afterwards 'entered the agricultural service, he was resolutely opposed. This inducement, like the provision of pensions under the Civil Service scheme for the retention of officers in the service, he regarded as coming within Sir James Currie's definition of "attracting candidates by means of well-baited out otherwise poor booby-traps"

Various other means of stimulating recruitment to the overseas services were discussed. It was pointed out that various post-graduate scholarship schemes in existence have been successful in this regard. Those scholarships provided by the Government, tenable at the Imperial College of Agriculture at Trinidad, have already provided a number of officers for the colonial agricultural services in the Tropics. The scheme of the Empire Cotton Corporation has also been successful in obtaining men for cotton research in various On the other hand, no success has so territories far attended the efforts of the Australian Commonwealth Government to obtain recruits for certain biological services by the grant of sımılar scholar-The Commonwealth offered post-graduate scholarships to the value of £300 a year for two years, with £150 travelling allowance, in addition to the payment of all special fees in connexion . with study. Some of these scholarships were offered to enable students to specialise in mycology and genetics. On the completion of their course, they were to be guaranteed at least three years employment under government at a minimum salary of £400 for the first year, £450 for the second. and £500 for the third. No applications were received for these scholarships. This was attributed to the past neglect of the agricultural services by the Australian Government and the failure of the people of Australia to appreciate the need for agricultural research.

Generally speaking, the discussion on training and recruitment was disappointing. It is true that much that needs saying has been said several times already in the past twelve months at gatherings of Imperial delegates, so that it was difficult to escape the platitudinous But since every representative of the Home Government present subscribed to the view that the Imperial Agricultural Research Service must provide an attractive career for first-classmen, if it is adequately to fulfil its prescribed functions, it is reasonable to expect that they should have defined its attractiveness in specific terms, and stated what further financial provision the Government is prepared to make, and what financial support has been promised or is expected from the Dominions and non-self-governing Dependencies, for the effective carrying out of the schemes submitted to the delegates for their consideration. It is to be hoped that some definite statement of this character will be made before the break-up of the Conference

# Cambridge under the New Statutes.

THE Vice-Chancellor, in his recent address at the commencement of the academic year at Cambridge, referred to the heavy strain which has fallen during the past year upon the administrative officers of the University—the Registrary, the Secretary of the General Board, the Treasurer, and, we may add, the Vice-Chancellor himselfand upon the members of various boards and committees. When 1000 pages of ordinances have to be recast to meet the requirements of new statutes, the labour involved must necessarily be extremely heavy. It may not be without interest to inquire after a year's working how far the results obtained justify not only last year's work, but also the heavy work involved over a period of years by the labours of the Royal Commission and the subsequent Statutory Commission.

What are the gains of the new scheme? The first one that strikes the eye at once is the feeling of security that the younger married 'don' has gained through the existence of a pension scheme of the same type as holds in the other universities of Great Britam. This means a comparative freedom from serious financial anxiety, and it makes easier the free interchange of teachers between Cambridge and other universities. Coupled with this is the advantage to the University which must accrue from a scheme which ensures the retirement of the teaching staff on reaching an age limit. Opinion will vary as to the proper age for retirement and the benefit that comes from a rigorous compulsory scheme, but it is clear that the scheme is, on the whole, a definite improvement on the old order of things.

Financially, many teachers in the University also benefit by the increased stipends which the annual grant to the University secured by the Commission has made possible. University stipends still lag behind the corresponding figures for professional careers outside, but the disgrace of the charity pittance awarded in the past to distinguished teachers has been stopped. It is for the University to watch that fresh developments are not marred by inadequate financial arrangements. This may check some of the valuable growths which in the past have come from poor beginnings; an

enlightened policy should see to it that such growth should be encouraged but with a start on a better basis.

The real gain of the Commission is that the University has now secured control of the development of its educational policy to an extent that was impossible before. The General Board of the Faculties, with its control over the finances of the purely teaching side of the University, has become the most important body in the University faculties, acting through their appointment committees, have control of the appointment of new teachers and are not so dependent as before on the chance appointment by the colleges of members of college staffs It is significant of the change how many of the vacancies of the past year in lectureships have been filled by candidates from outside This widening of the field must be a Cambridge pure gain to the University.

This would not be the case if the chances of promotion of the best sons of Cambridge to office in the University were blocked by the new scheme It may be that the process of co-operation between faculties and colleges in making their staff appointments has not yet been fully explored. The ideal scheme by which the University and the college should each take its share in supporting the man who divides his time between the two of them may take some time to hammer out, but the new statutes make such a scheme possible and practicable. Goodwill and organisation will do the rest.

Among other gains requiring mention are the opening of most University prizes, scholarships, studentships, and teaching posts to women, the improved financial position of the University Library, the easing of University taxation on the smaller colleges—here it must be admitted at the expense of the larger and richer foundations—and the official recognition of research as part of the University's duty.

There are necessarily difficulties, and here and there doubts and regrets. It is incumbent on those responsible not to let organisation become dominant and not to press the professors with too much departmental administrative work. The Vice-Chancellor, we believe rightly, attributed the comparative lack of discussion of recent changes in the ordinances to "a disposition to settle down to work and to put the new Statutes of the University and the Colleges to the test of practice." The University may well spend a year or two in rounding off the fruitful work of the Commission and making quietly the further changes which experience shows to be desirable and necessary.

#### Catalysis.

(1) Die Katalyse in der organischen Chemie Von Paul Sabatier Nach der zweiten franzosischen Auflage, übersetzt von Dr. Berthold Finkelstein Mit einem Literaturnachweis für die Jahre 1920 bis 1926, bearbeitet von Dr. Hans Hauber. Pp. xi+466 (Leipzig Akademische Verlagsgesellschaft mb. H., 1927) 24 gold marks.

(2) Catalysis in Theory and Practice. By Eric K Rideal and Prof. Hugh S. Taylor Second edition. Pp. xv+516. (London: Macmillan and Co, Ltd, 1926) 20s. net.

YATALYSIS is a subject which has always excited the interest of chemists-sometimes, indeed, their prejudices and passions. There is one point, however, on which they are probably all agreed, namely, that the association between the catalyst and the substances the reactions of which it catalyses is of so specific a nature that it is proper to apply the term 'chemical.' On the other hand, to understand the mechanism of the large class of chemical reactions which take place in contact with solid catalysts, it is necessary to inquire into the physical nature of the interfacial region where the surface catalysis takes place, and this introduces all the phenomena of 'adsorption.' For some purposes it is more important to know about the adsorption equilibria than about the nature of the forces which hold the adsorbed molecules to the surface; and there has occasionally arisen a quite unnecessary distinction between 'chemical' and 'physical' theories of catalysis. In recent years, however, Langmuir has done much to dispel the idea of any such antithesis.

The truth about eatalysis has many aspects, one or other of which becomes of predominating importance according to the problem under consideration

There are two great objects: one is to arrive at an understanding of the nature of chemical change in general, and the other is to be able to control specific reactions for particular ends, possibly industrial. The two books under review are quite different in scope and method. That of Rideal and Taylor is of a quite general character, and deals with both the chemical and physical aspects of catalysis and with its industrial applications, that of Sabatier is written entirely from the specific chemical point of view.

(1) "La Catalyse en chimie organique" is already well known to most chemists either in the French edition or in the English translation by Prof. Reid. It is an inexhaustible source of Enformation about the multitudinous organic reactions which can be catalytically controlled. These reactions must be regarded as forming almost a separate branch of chemistry, and one which is becoming yearly more important. It is only necessary to think of the convenient catalytic process for the dehydration of alcohol to ethylene, compared with the traditional procedure, to understand what industry owes to catalytic chemistry.

It is often possible to make at least a shrewd guess at the kind of catalyst which will be most effective in provoking some desired reaction. Although most of the information about catalytic organic chemistry is purely empirical, nevertheless the rague outlines of general laws are in places dimly discernible Definite rules, which would enable catalytic influences to be predicted a prion, cannot of course be formulated, but Sabatier succeeds in bringing many hundreds of reactions into a degree of co-ordination which is surprising. The picture he presents is not more chaotic than that, say, of inorganic chemistry fifty years ago. The analysis and arrangement of the material is masterly, and admiration is increased by the reflection that a very large portion is derived from Sabatier's own researches.

It is interesting to read the statement that Sabatier's own work on catalysis has been guided by the hypothesis that unstable intermediate compounds between the reacting substances and the catalyst are always formed. In the introductory part of the book, which occupies about fifty pages, he develops a general theory based upon this idea, and shows convincingly the fundamental part played by specific chemical interaction. This aspect is a very important one, indeed all-important, since Sabatier is concerned solely with the nature of reaction products, and not at all with the kinetic problems connected with the mechanism of reactions, or with the relation between reaction rate and concentration. To deal with these, however, it would have been necessary to take into account the physical chemistry of the processes in a manner similar to that of Langmuir and others.

For the purposes of his treatment, then, Sabatier has quite rightly laid all the stress on the specific chemical influences; but it must be remarked that for the physical chemist in search of examples on which to test his theories, this book provides the best storehouse of raw material that could be imagined.

After three introductory chapters of a general nature, there follows a classified survey of different

types of reaction, beginning with isomerisations, polymerisations, and condensations. The following chapters deal in order with reductions, hydrations, hydrogenations, various decompositions, dehydrogenations, dehydrations, the decompositions of acids and esters, the splitting off of halogen hydrides, the decomposition of hydrocarbons, and the hydrogenation of fats.

The translation of the French text appears to be accurate, if here and there very slightly on the side of freedom, and the German edition possesses an index, the absence of which was an almost intolerable disadvantage of the original. This disadvantage is specially felt in what is in some respects a work of reference. The translation contains 83 pages of additions, covering the years 1920–1924, and a synopsis, not very complete, of papers which have appeared since 1924. In the theoretical part of this appendix are two scanty references to 'Longmuir.'

(2) Since the original edition of 'Catalysis in Theory and Practice' was published, considerable advances in the theoretical aspects of the subject have been made, and industrial applications have developed and multiplied. The theoretical parts have been completely re-written for the new edition, and much additional matter relating to modern developments on the practical side has been put in.

Two introductory chapters deal with the early history of catalysis, and 'criteria of catalysis.' Then general theories about the nature of chemical change are discussed under the headings 'Homogeneous Reactions,' and 'The Theory of Heterogeneous Catalytic Reactions,' homogeneous reactions providing a standard with which catalytic reactions may be compared and contrasted. The subjects of promoter action and catalyst poisons are then dealt with, after which various chapters deal with the applications of catalysts to processes of oxidation, hydrogenation, and so on.

To the reviewer the most interesting parts of the book are, perhaps, those dealing with technical processes. There is, for example, an excellent discussion of the general problem of the reduction of the oxides of carbon, with an account of the modern methods of producing methyl alcohol from water gas. In this, and other similar examples, the authors have shown the application of the theoretical principles to practical problems in an illuminating way.

Information is to be found in different parts of the book on such varied matters as the cracking of oils, the production of synthetic rubber, the hydrogenation of fats, and the production of aniline black.

It is always a difficult problem, in a book which aims at completeness, to decide how far the author should merely quote the work and views of others, and how far he should criticise and re-interpret On the whole, Rideal and Taylor have compromised well between the possible extremes.

No book dealing with a rapidly developing subject could be written every page of which would compel unqualified assent On p 82, for example, it is stated that to account for proportionality of reaction rate to a fractional power of the pressure in a heterogeneous reaction, it is necessary to assume that each molecule of one of the reacting gases occupies some definite integral number of elementary spaces on the lattice of the There is a much simpler explanation solid. When the degree of adsorption of a gas like stibine is large, the rate of its chemical change is independent of the pressure; when the adsorption is small, the rate is directly proportional to the first power of the pressure. For intermediate degrees of adsorption, therefore, the rate of reaction must vary as some fractional power, which, in point of fact, is never quite constant.

The production of the book is very good indeed It is perhaps a pity that more care was not taken over proper names; it was, for example, 'Knietsch,' and not 'Kneitsch,' who did pioneer work on the contact process, and 'McC Lewis' is rather colloquial. These minor blemishes should be removed when possible from a book which will be of importance to all chemists for some time to come.

#### The Calculus of Tensors.

The Absolute Differential Calculus (Calculus of Tensors). By Prof. Tullio Levi-Cività. Edited by Dr. Enrico Persico. Authorised translation by Miss M. Long. Pp. xvi +450. (London and Glasgow: Blackie and Son, Ltd., 1927.) 21s. net

DHE "Lezioni di calcolo differenziale assoluto" by Prof. Levi-Cività were published in Italian in 1925. This account of the foundations of the absolute differential calculus has now been translated into English. Miss Long has thus conferred a benefit upon British mathematicians for which they will be very grateful. The subject is of fundamental importance in the applications of mathematical methods to modern theoretical physics the treatment is as masterly as can be expected, coming as it does from the lecture notes of one of the out-

standing exponents of the subject and one of the outstanding contributors to its development, the translation is excellent, combining, as Prof. Levi-Cività says in the preface, "scrupulous respect for the text with its effective adaptation to the spirit of the English language"

It is more than a mere translation, however, that we have before us now More than 150 pages are devoted to two new chapters, written specially by Prof Levi-Cività, dealing with the fundamental principles of Einstein's general theory of relativity, including as a limiting case the special theory, as an application of the absolute calculus. More than one-third of the book is therefore new, and it is a privilege to British mathematicians to have this addition to the original contents published in the English language. This treatment of the theory of relativity possesses distinctive features, which give it added value. The present writer has tor a long time thought that the study of relativistic mechanics should be presented on the basis of the classical Newtonian mechanics. This would have obvious advantages, the most important being that the essentials in the transition from the conceptions in the classical dynamics to the conceptions in the relativistic dynamics could be presented clearly and effectively, instead of being lost in a maze of optics and electromagnetics. Further, it is surely reasonable to claim that the study of the spacetime manifold is fundamentally a kinematic exercise, although the causes which have led to the modern view of space-time are derived from astronomical, optical, and electromagnetic experiences.

Prof Levi-Cività has adopted this viewpoint. He traces the relativistic evolution of mechanics, including geometrical optics, which in the theory of relativity is based upon the conception of a light ray as a special case of the path of a massless particle. He also adds another distinctive characteristic in the fact that he does not lay down the postulates of relativistic mechanics in abstract form, as so many new laws introduced arbitrarily, but proceeds inductively from the classical mechanics to discover modifications which are forced upon us if we take account of the principle of relativity.

Starting off with Hamilton's principle for the motion of a free particle, Prof Levi-Cività first shows that it is possible to apply the same treatment to the time co-ordinate as to the three space co-ordinates of the particle, with reference to the variational equation  $\delta \int \mathbf{L} dt = 0$ . Introducing the form  $\mathbf{L}/c^2 =$ 

$$1 - \sqrt{1 - \frac{v^2}{c^2} - \frac{2U}{c^2}}$$
, which for a very large value of  $c$ 

veis approximately the same as  $L = \frac{1}{2}v^2 + U$ , the classical form of the Lagranian function, the equation  $\partial_1 ds = 0$ is obtained, where  $ds^2$  can be expressed in terms of any four co-ordinates as a general quadratic form. The results of the special theory of relativity follow at once by putting U zero, and the author deduces the Lorentz transformation and all its familiar consequences Further, the extension to spacetime manifolds differing from the pseudo-Euclidean space-time in the special theory is a comparatively simple conception, the world lines of a free particle being the geodesics in its space-time continuum. Particular attention is devoted to geodesics of zero length, or light rays, where s cannot be used as the independent variable. The equations of motion of a continuous system are obtained in the same inductive manner and the introduction of the energy tensor justified

Having defined the Einstein tensor and the gravitational tensor in the older form, with divergence zero, Prof. Levi-Cıvıtà writes down Eınstein's equations of the gravitational field (without the cosmological term) He at once proceeds to deal with the statical problem, thus separating the timelike from the space-like terms, and shows how to a first approximation the Newtonian field is obtained. After the crucial phenomena 'the author attacks the problem of fields having spherical symmetry, dealing with the Schwarzschild, the Einstein, and the de Sitter solutions, and introducing the cosmo-No reference is made to Einstein's logical term new form of the equations of the gravitational field, which does not affect the field in empty space, but introduces modifications into the field inside matter.

Of the large number of books that have appeared in the English language on the theory of relativity, very few have had anything very original to contribute Prof. Levi-Cività's book in its English translation is a notable addition to the literature of relativity.

S Brodetsky.

#### Two Vienna Biologists Abroad.

Im Lande der aufgehenden Sonne. Von Prof Dr. Hans Molisch. Pp. xi+421. (Wien und Berlm: Julius Springer, 1926.) 24 gold marks.
Amerikafahrt: Eindrucke, Beobachtungen und Studien eines Naturforschers auf einer Reise nach Nordamenika und Westindien Von Prof. Othenio Abel. Pp. ix+462. (Jena: Gustav Fischer, 1926) 24 gold marks.

BOTH these books are by Viennese biologists, who describe their observations during tours of one to Japan and of the other to America.

Prof. Molisch was from 1922 until 1925 on the staff of the Botanical Section of the Biological Institute of the Sendai University in Japan He has already, ın his 'Pflanzenbiologie in Japan, recorded his special observations, and in this book writes of his journeys to and fro and in Japan, as he puts it, as a "globe trotter." He is, however, a highly trained, skilled observer, and he writes an interesting account of his vovages out and home, and of the various phases of Japanese life. He describes, amongst other topics, life and sports at the Japanese universities and schools, the theatre, the magic mirror, fishing by cormorant, the hot springs, the ascent of Fujiyama, the aboriginal race—the hairy Amu, the earthquake of 1923, and Japanese horticulture, fruits, and vegetables.

Prof. O. Abel's account of his visit to the United States and some of the West Indian islands in 1925, at the invitation of the International Education Board, contains more original matter. He is professor of palæobiology and visited many localities famous for their evidence on geological ecology, and he expresses on their problems a competent, independent judgment He visited the American museums rich in fossil vertebrates, he examined the quarries in Connecticut famous for their Triassic footprints; his visit to the mangrove belts in Florida and the West Indies leads to the conclusion that the Flysch of the Alpine belt, which has been regarded as the deposit of mud volcanoes or of deep seas, is the mud of ancient mangrove swamps, deposited when Central Europe consisted of a group of islands and had a tropical climate; in Florida he examined the beds at Vero which have yielded remains of fossil man, and concludes that the man was not as old as the associated fossils; he discusses the West Indian fauna and explains the various continental visitors to the islands not by land bridges but by mangrove bridges, and his interesting chapter on this problem illustrates the extent to which biologists, whose conclusions depend so largely on negative evidence, overlook the direct tectonic evidence. In Western America, Prof Abel visited the Grand Canyon and the Brea deposit at Los Angeles which has yielded such a rich Pleistocene mammal fauna, and also the fossil quarries of Nebraska; there he also examined Dæmonelix, an obscure fossil which has been regarded either as due to a burrowing animal or to plant roots; and he advocates the latter

Both books are richly illustrated by excellent photographs, and many of these by Prof Abel are of the specimens he collected. He gives many references to the literature, so that the book is a useful guide to recent contributions to many problems in American geology. In his account of the bone beds of Nebraska he explains their origin by the crowding of the animals on to hill-tops at times of flood: and in reference to the opposite explanation, that they were bogged beside drying pools in time of drought, he quotes a sentence which he attributes to W. K. Gregory instead of to the present writer.

J. W. G

#### Our Bookshelf.

Eolus: or The Future of the Flying Machine. By Oliver Stewart. (To-day and To-morrow Series.) Pp 96 (London: Kegan Paul and Co., Ltd; New York. E. P. Dutton and Co., n.d.) 2s. 6d. net.

THE ' To-day and To-morrow' series has a reputation of brilliance and provocativeness. Mr. Oliver Stewart's account of the future of the flying machine amply maintains this reputation. The writing is clever, the argumentation is fearless, and the prophecy is unhampered by any hesitation to speculate on the barest foundations. In civil aviation, Mr. Stewart foresees a severe struggle between the present-day type of fixed-wing aeroplane and the moving-wing flying machine of which the autogyro is a forerunner. He concludes that the moving-wing type will prevail for short-distance flight, while the fixed-wing machine, in the form of monster flying boats weighing a thousand or more tons, will prevail for long-distance and transoceanic flight. An amusing forecast of the relationships between the police and sporting aviation is followed by a fantastic and gruesome account of the future battle in the air round and over London. Why has nobody yet written on the renewed sense of dignity and privilege that the provincial will acquire as the result of the concentration of aerial warfare round the large centres of population?

Mr Stewart seems to have considerable objection to statesmen and financiers. It may be of interest to scientific workers to discover that the author objects to them too: "... scientists have demonstrated that the world is flat, that it is round, and that it is oblong. In the future they will demonstrate that it is rectangular." This is pretty nonsense, and the author bases much of his interesting prophecy on the results of scientific investigation. Mr. Stewart does not believe in the future of the airship.

S. B

Theory of Vibrating Systems and Sound. By Dr. Irving B. Crandall. Pp. x+272 (London: Macmillan and Co., Ltd., 1927.) 20s. net.

The reader of Rayleigh's classical treatise on the theory of sound cannot but feel that the subject is more of theoretical than of practical interest. It is true that the theoretical results have many illustrations in certain of their musical and technical aspects, but one does not feel that the theory has had much influence on the design work of the constructional engineer. In recent years, however,

great progress has been made in applied acoustics, more especially in connexion with the problems of telegraphy, telephony, sound transmission and reproduction, and certain parts of the classical theory have been extensively employed to analyse and explain the problems and results that presented themselves in the technical developments of these subjects

In the book before us, the late Dr. Crandall, who was a member of the technical staff of the Bell Telephone Laboratories in New York, has presented an account of those parts of the theory which have proved of service to the constructional designer The theoretical side of the subject is treated thoroughly—on the lines of Rayleigh's treatise—without, however, too great insistence on mathematical detail, but also without that slovenliness and circumlocution so familiar in technical works dealing with mathematical subjects The best parts of an altogether good book are those essential connecting links in the mathematical argument where the physical assumptions underlying the theory are examined from the point of view of their practical possibility and where the limitations and usefulness of the mathematical results are discussed in their physical and technical bearing. To a theorist these parts make very satisfying reading, and to the practical man they more than justify the application of somewhat complex mathematical analysis to the technical problems of the subject.

The book is well written and can be strongly recommended as an up-to-date text-book of the subjects with which it deals. It is replete with bibliographical references even of the most recent developments of the subject, and is produced in a style worthy of the publishers' name that it bears

GHL.

Crashing Thunder: the Autobiography of an American Indian. Edited by Paul Radin Pp. xxvi+203. (New York and London · D. Appleton and Co., 1926) 10s. 6d. net.

This autobiography of one of the Winnebago Indians living on the Nebraska side of the Missouri River, is a remarkable document. It may be regarded either as a piece of anthropological evidence or as material for psychological study. Its engaging frankness and entire absence of a moral viewpoint are illuminating. At the same time it must be admitted that from neither point of view do the conditions which this record reveals seem such as are conducive to the welfare and preservation of the Indian, if they can be regarded as typical. It is perhaps significant that m seventeen years a Presbyterian mission had in 1909 converted one family only. This suggests a conservatism which adds to the value of the autobiography as a record of tribal custom and tradition. Anthropologists who have worked in the field are well aware of the difficulty of getting at the subjective side of the information they seek. In this document custom, ritual, and belief take their proper place as integral elements in proper perspective in the everyday life of the individual.

# Radioactive Haloes. Possible Identification of 'Hibernium.'

Some years ago, Prof. Joly (Proc. Roy Soc., A, 102, 682, 1923) discovered radioactive haloes which could not be a scribed to any known radioactive product. One class, not unlike thorium haloes, he called X-haloes: a second class, of radu less than those of other haloes, he called 'hibernium' haloes, hibernium being the suggested name for the new radioelement causing the halo. Recently, S. Ilmori and J. Yoshimura (Sci. Papers Inst. Phys. Chem. Res Tokyo. 5, 11; 1926) have found a class of haloes not unlike X-haloes which they call Z-haloes. They suggest that the X-haloes and possibly the haloes ascribed by Prof. Joly to radon are identical with these, and that they are due to products of the actinium series. Z-Haloes have sometimes two inner rings smaller in radius than any caused by a known radioactive product, and these they ascribe to two uranium isotopes at the head of the actinium series with half-value periods of the orders of 1012 and 1023 years. They also state that their work on Z-haloes definitely establishes that the actinium series originates independently of the uranium series

The Japanese workers are, I think, probably right in their ascription of the Z-haloes to actimizing products, but in identifying radon haloes with actimizin haloes, and in ascribing the two very small rings to isotopes of uranium, they have missed an important point. The actimizing series cannot be regarded as originating independently of the uranium series in view of the strong experimental evidence to the contrary. Moreover, if the actimizing series has uranium isotopes, as they suggest it has, how did these get separated from uranium itself to form a halo unmasked by that due to uranium and its products? They have evidently not considered this. The only answer I can suggest is that the uranium isotopes which originate the actimizing series giving the Z-haloes are end-products of elements of atomic number greater than 92 and so have not necessarily mixed with ordinary uranium.

I think the explanation of the unexplained rings and haloes is probably simple and involves two things. isolation of radioactive products from known minerals by chemical agencies, and the possession of feeble radioactivity by some of the so-called end-products.

It is known (W. Marckwald and Russell) that uranium minerals may be so altered by agencies like percolating water that, while the presence of the equilibrium amount of ionium testifies to their great age, they are anomalous in possessing no lead, a fraction only of their equilibrium amount of radium and, as unpublished work of nune shows, a fraction only of their protoactinium Let us consider what is likely to occur if each of the different elements present in a primary uranium mineral were isolated by chemical agencies and afterwards formed a halo in the mica with the particles they emit. Isolation of element 91 would isolate protoactinium and lead to the formation of the halo characteristic of the actinium series; isolation of elements 90 and 88 would lead to uranium haloes in different stages of development, isolation of element 89 would lead to actinium haloes minus the

ring due to protoactinium; isolation of element 86 would lead to the characteristic radon halo discovered by Prof Joly, isolation of elements 84 and 83 would lead to a single ring characteristic of polonium; isolation of element 82 would perhaps lead to the polonium ring and to any rings due to possible a-particle activities from the end-products; no halo is to be expected from the isolation of the quick-changing products of element 81. Thorium minerals may be similarly considered

Now it is not unlikely that some of the end-products of atomic number 82 may be found to be feebly radioactive For theoretical reasons too lengthy to be given here I find that possible end-products of atomic masses 204, 205, 206, and 207 are unlikely to possess any radioactivity, while those of masses 210, 209, and 208 may be feebly radioactive, and that, of these three, actinium-2, of mass 209 (NATURE, Sept. 17, p. 402), is likely to be more unstable than the two others. Now, for a given half-value period, an 'α-rayer' of the actinium series has a larger range than an 'a-rayer' of the thorium or uranium series. The a-particle from the product of mass 209 might therefore be expected to have a longer range than those from the two other products, but shorter than the a-particles from uranium or thorium.

The identification by S. Limori and J. Yoshimura of Z-haloes with X-haloes was made, not by a comparison with their own of Prof. Joly's published measurements, but from observations of his photographs. (The published measurements of both sets ot haloes do not, in fact, agree well ) For a reason I know not, the radu of the rings of uranium and thorum haloes measured by the Japanese agree closely with those to be expected theoretically, while those of Prof Joly are generally smaller, the deviation from theory being the greater the shorter the range of the a-particle A straight-line relation appears to connect the theoretical with his observed radu of the rings, and, using it, I have calculated the radii of the rings of Prof. Joly's unexplained haloes to compare them with the other measurements. The smallest rmg observed has then a radius of 7, 5 4, and 6.3  $\mu$ in hibernium-,  $Z_1$ -, and  $Z_2$ -haloes respectively, and the second smallest ring has a radius of 11.0, 10.5, 10.8, and 10.7  $\mu$  in two different sets of X-haloes, in a  $Z_1$ -halo and in an unnamed halo respectively. Each of these rings is too small in radius to be ascribed to any active radioelement. The larger of these I ascribe to actinium- $\Omega$  (mass 209), and the smaller to both radium-\(\Omega'\) (mass 210) and to thorium-\(\Omega\) (mass 208).

On this view, if lead alone were isolated from a uranium mineral, a single ring, the larger of the two small rings, would be observed, since the concentration of radium- $\Omega'$  relative to that of actinium- $\Omega$  is very small. This would explain Prof. Joly's unnamed halo, the single ring of which has a radius of about 10 μ. Similarly, if lead alone were isolated from a thorium mineral, the smaller of the two rings would be formed. This would explain the hibernium ring. If protoactinum were isolated, the resulting haloes would have rings characteristic of protoactinium and its products without either of the smaller rings. This would explain the majority of  $Z_1$ - and  $Z_2$ -haloes. If lead and protoactinium were simultaneously isolated from uranium minerals, the resulting haloes would show the rings of protoactimum and its products and the larger of the two small rings. This would explain the X-haloes. If, finally, the uranium minerals contained thorium, as many of them do, there would be, in addition to the actinium rings, the smaller of the two small rings. This might explain the remainder of the  $Z_1$ -haloes.

I do not stress these identifications at the moment,

but I submit that the two points stated above afford a solution of these unidentified rings more probable than the ascription of Z-haloes to undiscovered and unlikely radioactive products and, as S. Rosseland (Nature 109, 711: 1922) suggested, of hibernium to an element of atomic number approximately 40.

If these views are correct, the disintegration series are partly extended to the element mercury. Inbernium is identified as thorium- $\Omega$  (or one of the two thorium- $\Omega$ s), the half-value period of actimum- $\Omega$  calculated from Geiger and Nuttall's relation is of the order of  $10^{16}$  years.

Christ Chuich, Oxford, Sept. 16.

#### Changes in Herring Shoals.

After the War, extended herring investigations were commenced at Cullercoats, and since 1919 there has been a continued series or observations as to the size, age, sexual development, and growth of the fish from some of the most important shoals in British waters. It is possible to point to three well-defined changes in the shoals, and the evidence from growth data indicates that these have been brought about by migration. There is a possibility that these migrations have been due to hydrographic conditions

Towards the end of 1920 there was a movement of some of the North Sea herrings to or towards oceanic conditions This movement was continued in 1921, in which year the whole of the east coast fishery was a failure (Reports, Dove Marine Laboratory). The years 1920-21 were marked by an abnormal invasion of Atlantic water into the North Sea. In 1923 the migrants of 1920-21 returned as spring spawners to the grounds off the north of Scotland and about the Shetlands; some few made their way so far south as the Berwickshire coast. Their scales showed a North Sea growth for the first three years and an oceanic growth for 1921-22. In the same year old fish, six winter rings and more, practically disappeared from the shoals of the north of Scotland, Shetlands, East Anglia, and north-west Ireland; the scales of fish from Howth, the Smalls, and St. Ives indicated extended migrations (*ibid.*). The white fishery was poor on practically all our fishing grounds.

Johansen directs attention to an abnormally strong inflow from the Skager Rack to the Kattegat in the spring of 1923 (Jour. Con. Per. Inter. Explor. de la Mer. vol. 1, No 2) and to increased catches of mackerel from Danish waters (Medd. Komm. Harund., Fisk., Bd. 7, No. 8). Watkins, in his report on Cardigan Bay shoals, quotes Lloyd as to the invasion of Cardigan Bay by oceanic forms in the summer of 1992.

1923.

In January 1926, extraordinary numbers of young fish (1924 year-class) appeared off north-west Ireland, and trade papers reported the invasion of the lochs of western Scotland by shoals of small size and poor quality. About the north of Scotland, the 1920 year-class and younger fish failed to appear in sufficient numbers to make anything but a poor spring fishery, and the same applies to the Berwickshire coast (Repts., Dove Mar. Lab.). In August there was an exceptionally good fishery off the Northumberland coast. Following this we have to note a marked difference between the shoals of north-western Ireland and northern Scotland in the early months of 1927. Previously the relative values of the different year-classes were the same for these grounds, but now the 1923 year-class is predominant about northern Scotland and that of 1924 about north-western Ireland. In Shetland waters the year-

classes which had been good previously are now poor, and the poor year-classes are good. This is illustrated by the age composition of two samples given below.

#### WINTER RINGS (PERCENTAGES).

The Northumberland shoals have been marked this year by abnormally high percentages of fish with 2 winter rings. They are a year vounger than usual Reports from friends in the herring trade state that from Wick to below Scaiborough the fish have been small It will be of interest to see if the East Anglian fishery is marked by large numbers of young fish in October and different relative values of the older year groups later in the season.

It is evident that the herrings have been swimining differently and the large catches of salmon off the Tyne 1926-27, and the taking in August off the Tyne of cod more than 40 lb when gutted, suggest that

other fish have been doing the same

The Dana in August 1926 took 297 larval eels from the southern part of the Faroe-Shetland channel, and Schmidt (Jour Con Per. Inter. Explor. de la Mer, vol. 2, No. 1) gives these an age of  $2\frac{1}{1}$  to  $2\frac{1}{2}$  years. The International Ice Patrol reported for 1924 an absence of ice and fog, warmer water than usual—5° to 6° F. above normal in March—over the Grand Bank Region, and for the first time a complete cessation of the flow of Arctic water southward along the east side of the Bank during the ice season. The Annual Report, Department of Marine and Fisheries, Newfoundland, 1924, states that Labrador cod were on the grounds before the fishermen were ready, and that whilst the southern Labrador cod fishery was poor, that of northern Labrador was excellent Huntsman ("The Ocean around New-toundland") records exceptionally warm water over the Grand Bank early in the season of 1924, cod farther in than usual on the banks off Nova Scotia, large quantities of haddock close inshore off Nova Scotia and New Brunswick, the failure of the cod fishery of the Belle Isle region, and the capeling farther north on the Labrador coast than ever before. Jensen ("On the Fishery of the Greenlanders" records for 1924 the presence of great quantities of large cod in Davis Strait in June, great shoals of small cod off western Greenland at the end of summer, and for the first time in seventeen years the presence of Gadus virens in Greenland waters From the statistics of the cod fishery given by Jensen, it would appear that in 1924 the cod population of western Greenland split, one half going north, the other south.

There is evidence that in 1924 the fish of the north-western Atlantic were swimming differently and that their movements were influenced probably by hydrographic conditions. The connexion between the happenings on the other side of the Atlantic in 1924 and changes in British waters, indicated by the herring shoals as beginning early in 1926, is perhaps worthy of consideration

At present the chain of events would appear to be as follows: An abnormal activity of oceanic waters in 1920-21 probably due to lunar influence; a cumulative effect or a rebound from the Arctic accounting for the happenings of 1923, the production of a mild Arctic winter, 1923-24; a diminution of cold currents entering the north-west Atlantic in the spring of 1924, followed by changes in the north Atlantic warm currents which influenced British waters and fisheries early in 1926. B. Storrow.

Dove Marine Laboratory, Cullercoats, Sept. 24.

# The Crystalline Nature of the Chief Constituent of Ordinary Coal.

The examination of thin sections of coal with the petrological microscope (see NATURE, Dec 25, 1926, p 913) has been extended to Terriary coals from Baluchistan, the Punjab Salt Range, and Assain. The observations previously inade on Paleozoic coals have been confirmed by the later investigations, except for the pleoch oism, which is deceptive and probably not actual

In every section which has been studied in ordinary transmitted light, practically all the bright coal and much of the dull coal layers seem to have the structure of polished wood and to consist of a madder-red coloured, translucent substance. If the section is thick or the illumination feeble, this substance is darker coloured or almost black. In very thin sections or with strong sunlight, this substance has a distinct golden yellow colour. Examined in plane polarised light, all sections show an exceedingly faint waxing and waning in the illumination of the coal substance throughout the movement of rotating the section. There is no definite darkening or lightening as a whole at certain positions, and thus pleochroism is evidently absent

Sections of bright coal cut parallel to the plane of lamination and examined between crossed Nicols show the coal substance to be isotropic. The section, although dark, is not absolutely dark between crossed Nicols Close attention, while rotating the section in this position, shows that every part of the substance goes absolutely dark at some point, but it lets a little light through in other positions. The total light coming through is, however, small, and the darkened section seems to be uniformly darkened even during the rotation of the slide. There is of course the same very faint continuous waxing and waning during the rotational movement, as was noticed for the illuminated section in plane polarised light.

All sections cut perpendicular to the planes of lamination and examined between crossed Nicols show the coal substance to have the crystalline character of a uniaxial mineral. The whole of the coal substance seen in the field of the microscope is moptical continuity as if parts of a single crystal. It has, on rotation of the section, a definite extinction, very distinct with really strong illumination, parallel to the lines of the laminæ. The extinction is not absolute at its darkest point, nor is the section very bright when the Nicols are at 45° to the laminæ. However, there is no doubt whatsoever about the extinction phenomena being quite clear in all the sections cut perpendicular to the coal laminæ.

The coal substance is seen to be somewhat granular under higher powers of the microscope. In some portions of the slides there is evidence of a cellular or woody structure. The presence of recognisable structure in the coal substance does not affect the optical phenomena at all. If a honey-comb was filled with opaline slica and a section made, the general appearance of the slice under the microscope would probably be similar. Stopes and Wheeler ("The Constitution of Coal," Department of Scientific and Industrial Research, 1918, pp. 20-21) have recorded an observation of this nature in the case of a piece of fossil-wood examined by them. The siliceous matter had permeated and filled the wood cells without destroying or replacing the tissues separating the cells of the original wood.

In addition to the main or chief constituent of coal, the section reveals the presence of three types of minor constituents: (1) Resinous bodies, (2) amorphous 'mineral charcoal,' and (3) morganic

matter Any one or more of these three minor constituents may be present in abundance and impart a distinctive character to the coal,  $e\,g$ , dull waxy or spore coal (bog head), dull silky coal, and coal shale being types respectively. Each of these minor constituents offers an attractive field for research. Their study is far more complex than the simple names suggest

The discovery that the chief substance or constituent in ordinary coal was probably liquid or a fluid jelly which has afterwards hardened affects the existing nomenclature of coal constituents. No terms based on lithological characters (e.g. vitrain, clarain, and durain) or on a botanical origin (e.g. anthraxylon and attritus) can have more than a descriptive significance. Such names may be convenient if restricted to the appearance or structure, respectively, of the coal, and not extended to the nature of the coal substance. The older, well-known terms, bright coal, dull coal, and mineral charcoal, with perhaps the introduction of such adjectives as silky, glossy, matte, waxy or resinous, and shaley, can be made just as explicit as any of the above terms for descriptive purposes. (See descriptions by Fermor, Memoirs, Geological Survey of India, vol. 41, pt. 2, 1914, pp. 180-181.)

A note of warning must, however, be sounded in regard to the naming of the chief constituent of coal. It is as certain as can be that this constituent permeates the coal and has crystalline properties suggestive of a definite substance. We are under no delusion that analyses of the purest forms of brown coal, bituminous coal, and anthracite clearly indicate a loss of carbon dioxide and methane from a composition, say, of dopplerite. There is little doubt that with loss of volatile matter the coal substance has not merely hardened, become denser and changed in appearance (lustre), but that there is an evident change in composition. Therefore in giving a name to this chief constituent we must remember this change of chemical composition. It would be simplest for the present, perhaps, to use the word coal substance, in a strict scientific sense, for the chief constituent of coal, using the general word 'coal' as it has always been used. CYRIL S. Fox.

Geological Survey of India, Calcutta, Sept. 7.

#### Origin of the Rio Tinto Ore Bodies.

AFTER a year's intensive study of the surface and underground conditions at the Rio Tinto Mines in the Province of Huelva, Spain. I have been led to a theory as to the origin of the great ore bodies in this region. As this theory or working hypothesis has already borne fruit, masmuch as it has led directly to the finding of several new ore masses, it is deemed worthy of brief mention here in advance of the full discussion which will appear later.

In the vicinity of the mines there are two masses of quartz porphyry. The southern mass is a sill which has been injected along the cleavage of the slate. To the north of this sill, and separated by slate, there is another porphyry intrusion which maps as a dyke. On its southern flank it either undercuts or reverses the dip of the slates. On its northern flank it has a conformable intrusive contact with slates, that is, the strike and dip of the porphyry-slate contact are the same as the strike and dip of the slaty cleavage. Within the porphyry area there are numerous isolated bands of slate. The North Lode group is entirely surrounded by porphyry. On the other hand, San Dionisio, Eduardo, and South Lode are on the south contact between porphyry and slate.

Planes is at the eastern nose of the dyke with immeral between its slate roof and the porphyry.

The porphyry, which is near a numeral mass, is fractured and also sheared. The shearing appears as an approximation to a rough irregular cleavage. The fracturing gives a coarse cross pattern and the fractures are now filled with pyrites, chalcopyrite, and gangue. The ensemble of these veinlets is called a stockwork.

The stockwork is always found below or to the side of the mineral, and extends both horizontally and vertically for considerable observable distances from the masses

I believe that the masses were fed from depth by the

solutions traversing these channel-ways.

In regard to the shearing and fracturing, it would appear that forces other than those usually termed orogenic, that is, large scale tangential compressive forces, must be called in to explain their origin. The reason is that any forces of sufficient magnitude to shear and fracture the porphyry would have pulverised the slates to a degree not seen in the areas around the dyke. It follows that one should look for the cause within the porphyry mass itself. Where stockwork is strongest there is less shearing and vice versa. Furthermore, the strike and dip of the shearing approximately parallels the contact of the porphyry and slate. These facts seem to indicate (a) that the shearing is the result of injectional pressure, and (b) that the shattering took place following the crystalhsation of the magma when torsional forces were brought into play by slight upward or downward movements of the semi-liquid magma beneath its chilled roof. Where a shear structure existed, the movement was taken up along the already existing lines of weakness, but where the magma had crystallised normally the result was a shattering. The pattern of the shattering on any plane resembles closely that which was produced by Daubree in his classical experiment on the torsional effects on a glass plate ("Etudes synthetiques de Géologie Experimentale." Paris, 1879.)

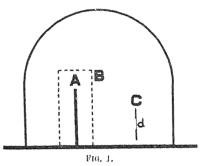

As the magma cooled, pressures were brought to bear on the interior of the porphyry mass and the mineral bearing solutions were caused to circulate upwards through the fractured zone. These solutions replaced the softened and communited state, which had suffered alteration by the intrusion of the porphyry, and to a certain extent the porphyry itself. It may be asked why all the slate at the slate-porphyry contact is not thus altered and therefore in a state favourable for replacement. The answer is that where the porphyry has cut across the slaty cleavage or where the porphyry has included keel-shaped masses of slate, it has had the opportunity of altering the slates. Where the porphyry has simply slid up along the slaty cleavage there has been little alteration, because the slate is almost impermeable to solutions in a direction normal to a cleavage plane.

G. VIBERT DOUGLAS Geological Department, Rio Tinto Mines, Spain, Sept. 1927.

#### The Electric Arc in High Vacuum.

Whatever the mechanism of the electric arc, we can scarcely expect an arc to strike and to persist under pressures so low as to render difficult the passage of a high voltage discharge. However, in the course of some experiments on the discharge of electricity through gases, it was observed that under certain conditions an electric arc carrying many amperes can be maintained in a vacuum as high as 0.001 mm.

The electrodes A, B, and C (Fig. 1) are placed under a large bell-jar of 12 litres capacity. Electrode A is a heavy rod or block of metal enclosed in B, an electrode in the shape of a box made of heavy metal gauze or perforated plate. Electrode C is composed of a circular plate and an insulated platmum. strip stretched across an opening in the plate; it may be used either as a cold electrode or as a Wehnelt cathode. Electrodes A and B can be connected to the 230 volt line, and electrode C to a source of high potential. When a vacuum is produced under the bell-jar and a high voltage discharge passed between C and B, an are strikes between A and B and keeps going after the auxiliary discharge is stopped. The higher the vacuum, the easier the are starts 0.001 mm, pressure, a p.d. of 60 volts across 4 and Bis sufficient to start the arc, at 0.05 mm 120 volts is necessary, while at I mm pressure a p.d. of 230 volts is not sufficient. During the passage of the are the pressure under the bell-jar naturally increases, but if the electrodes A, B, and C are previously freed from the occluded gases by a prolonged discharge

and the moisture in the vessel removed by phosphorus pentoxide, this merease becomes very small In one experiment, for example, an are carrying 3 amperes for 10 seconds raised the pressure to only 0.002 mm., and at this pressure, after the are had been interrupted, the high voltage discharge from electrode C still passed with difficulty, showing the characteristic green fluorescence on the walks of the bell-jar. The fact that with small potential differences practically unlimited currents can pass between electrodes A and B, while the low pressure makes it almost impossible for the discharge to pass from the electrode U in spite of the high potential applied, is very surprising, and indicates that the mechanism of the electric arc is radically different from that of an ordinary discharge.

The arc has been produced with copper, brass, ron, and aluminium electrodes. It shows the usual current-voltage characteristic, the p.d. across the electrodes dropping to about 20 volts when the current is increased to 30 amperes. When the arc strikes, a brilliant spot appears on the surface of the cathode and continuously changes its position as in

the case of a mercury arc.

An interesting feature of the arc is the unilateral relationship which the polarity of the arc must bear to the polarity of the auxiliary discharge between C and B. If C is an anode, the arc strikes independently of the direction of the field between its electrodes A and B, but when C is used as a cathode the arc strikes only when A is the anode in the arc circuit. This property of the arc has been successfully employed in some experiments in rectitying alternating current S. RATNER.

Physics Laboratories, Columbia University, New York, Aug. 30.

#### Coherence of the Reflected X-Rays from Crystals.

On Jauncey's theory (*Phys. Rev.*, **25**, 314; 1925) of the unmodified line in the Compton effect, an unmodified X-ray is scattered when the energy of the impulse imparted to an electron is insufficient to eject the election from the parent atom. In this case the impulse is presumably imparted to the atom The change of wave-length of the unmodified ray should thus be of the order of [(mass of the electron)/(mass of the atom)] x (change of wavelength of the modified line) It is generally assumed that no coherence occurs for modified scattering on account of the change of wave-length. In the case of unmodified scattering, however, it is assumed that coherence does occur, as, for example, in regular crystal reflection (see papers by Williams, *Phil Mag.*, 2, 657; 1926, and Jauncey, *Phys Rev.*, 29, 757; 1927) But how can coherence occur in unmodified scattering if there is a change of wave-length, however small? Perhaps there is no change of wave-length at all in unmodified scattering

Following the idea underlying Jauncey's interpretation of the unmodified line, the atom should not by itself receive the impulse of the scattered quantum unless the energy acquired from this impulse is sufficient to give at least one quantum of vibrational heat energy to the atom. According to Einstein's theory of specific heats, this energy is  $h\nu$ , where  $\nu$  is a frequency of the order of that of the reststrahlen from the substance in question The wave-lengths of two bands of these resistration from rock-salt are  $47\,\mu$  and  $54\,\mu$  (Wood, "Physical Optics," p 412), or, let us say, of the order of  $50\,\mu$  A quantum of this wave-length has an energy of 0 024 electron If we consider the  $K_a$  line of molybdenum reflected from the (100) planes of rock-salt in the  $n^{th}$  order, the energy of recoil given to a sodium atom by the impulse imparted by the reflected quantum is 0 0252 sm²  $\theta$  volt-electrons (see Compton, "X-Rays and Electrons," p. 267). Replacing  $\sin \theta$  by  $n\lambda/2d$ , the energy of recoil is  $4.02 \times 10^{-4} \cdot n^2$  volt-electrons Hence the ratio of the energy of recoil for each order to the energy of a quantum of reststrahlen is as follows:

 $\frac{n}{\mathrm{ratio}}$   $\frac{1}{0.017}$   $\frac{2}{0.067}$   $\frac{3}{0.15}$   $\frac{4}{0.27}$   $\frac{5}{0.42}$   $\frac{6}{0.60}$   $\frac{7}{0.82}$  The highest possible order of reflection according to Bragg's law is the seventh. The fact that the ratio is always less than unity indicates that the energy of recoil is always less than that of a quantum of thermal agitation, and this implies that the thermal agitation will not be excited. Presumably, therefore, the impulse is imparted to the crystal as a whole. There is thus no reason to anticipate an absence of coherence in the reflected rays.

This point of view leads naturally to the quantum interpretation of crystal diffraction as suggested by Duane.

#### Spectrum of Ionised Krypton.

The lines of the spectrum of krypton which appear under the influence of condensed discharge, were first carefully measured by Baly (Phil. Trans, vol 202, p. 183, 1903). Messrs. L. and E. Bloch and Dejardin (Ann. de Phys, vol 2, 1924) have recently studied the spectra of krypton developed with electrodeless discharges, and re-arranged most of the lines given by Baly, and also many new lines measured

by themselves, into groups of spectra appearing with varying excitations. Following the analogy with ionised neon, the spectrum of which was analysed by me some time ago. I have observed that the spark lines of krypton which appear at the lowest excitation show a considerable number of regularities. I give below three groups of terms, A, B, and C, such that A combine with B, and B with C, and account for a large percentage of lines. The values given are purely arbitrary, the deepest level so far discovered corresponding to 0.

	A	
0		4774 4
$2263\ 6$		5645.7
	B.	
21094 9	$25550 \ 4$	28891 5
21457 7	262727	29164.5
22952 1	272880	295324
23240 1	$27306\ 1$	
	C.	
44247 5	48970 1	$50526\ 3$
45053 8	490457	51607.5
48577 4	492272	$52245\ 5$
48620 0	497342	$52310 \ 1$

I have not yet succeeded in identifying the natures of these terms unambiguously. Zeeman splitting of some of the lines holds out the best promise of success in this direction. P. K. Kiehlu.

Physics Dept., Science College, Patna, India, Sept. 14

## The Diminution in Number of the Nodes in the Bivalents of Lilium.

The species of Lilium examined have twelve pairs of long chromosomes. The numbers of nodes in the bivalents of Lilium longiflorum (and Lilium regale) were counted at different stages, from the earliest prophase, immediately after the diplotene stage, to the diaphase; and also at the metaphase itself. These counts were usually made after pressing cyto-plasm and chromosomes from the cell. Such counts showed that the average number of nodes for the group of twelve chromosome pairs was 22.1 for the diaphase and metaphase, while in the earliest prophase it was found to be 39. Thus nearly half the nodes (43 per cent.) disappeared between the diplotene In L. longiflorum, pollen stage and the diaphase. mother-cells observed at stages between the earliest prophase and the diaphase showed different degrees of diminution in the number of nodes. In the four largest chromosomes of Hosta carulea, a similar reduction was observed, from 9 to 5 nodes. From the drawings of Newton (Linn. Soc. Jour. (Bot.); 1927) it can be estimated that there was a loss of nodes between the earliest prophase and the diaphase of somewhat less than one-half the number in Tulipa.

The nodes at the diaphase and first metaphase can be proved, in all or nearly all cases, to be chiasmas. This can be shown in *L. candidum* by pressing the netaphase bivalents flat, when the X-chiasmas are clearly visible. The question is, then, what is the nature of the nearly fifty per cent. of the nodes which disappear before diaphase? The writer considers that the majority of these are not half twists; as has, perhaps somewhat hastily, been concluded by the early cytologists.

### Invention as a Link in Scientific and Economic Progress.1

By Sir James B. Henderson.

NVENTION and discovery are so closely allied that they are often confused. In our common speech the two terms are frequently used as synonymous, and if one seeks an exact line of demarcation between them one finds it difficult, if not impossible, to distinguish one from the other in any but the most general terms. Both involve an increase in knowledge which may be great or slight, and may have an immediate effect or may take a lifetime or more to consolidate Both involve scientific Each may be only a happy idea, imagination the inspiration of a moment or in some cases an accident, but the testing of the idea and its final enunciation as a physical truth or as a finished invention may occupy many years Newton is reputed to have discovered the theory of gravitation on seeing an apple fall from a tree, but assuming that to have been the birth of the idea, we know that the completion of his discovery and the proof of the universal law of gravitation took the best part of his lifetime and involved the invention of new branches of mathematics to complete the

The dividing line between discovery and invention is, in very general terms, the same as between theory and practice, between the abstract and the concrete. Discovery is essentially an increase in man's knowledge of Nature and its complexities, and is therefore intangible. It may be a discovery of a new principle, a new element, a new and hitherto unknown quality or characteristic of a known substance, and so on, but the discovery, per se, has no regard to any particular practical application of the new knowledge. Invention, on the other hand, has its sphere in the practical application of knowledge, and the knowledge used may be new or may be as old as the hills. It may be, and it is often the case, that invention involves other discoveries which may be complementary to the original discovery and form its completion, or may be entirely unrelated to it and form the nucleus of a new branch of study It is possibly this fact, that the difficulties encountered in developing an invention often lead to new discoveries, which makes it so difficult to separate discovery from invention. I think, however, that this distinction in general terms is sound, that discovery is mental while invention is material, and while it is true that in the large majority of cases an invention is in its origin a mental conception, it is a conception of something material and practical, while a discovery begins and ends in the realm of the mind.

When one seeks to study the history of some of the great inventions, one begins to realise how exceedingly complex they are, despite their outward appearance of simplicity. As an example, take wireless telegraphy and telephony. No single person deserves the credit for its discovery

and invention. Maxwell, Hertz, Lodge, Crookes, Branly, Marconi, Jackson, Fleming, de Forest, Fessenden, and many others have contributed their share to its development, but the basis of wireless communication did not necessarily begin with Maxwell.

Hertz was the first to produce apparatus for transmitting and receiving wireless waves, and this apparatus was improved by Branly, Lodge, and many others, but for further progress finance was needed. The firsts steps to make a wireless telegraphic installation were taken in Italy by Marconi and in Great Britain by the Admiralty experiments carried out by Admiral Sir Henry Jackson, who was then a captain In this kind of competition money counts for much, and in the development of an invention having a commercial as well as a service aspect, a commercial firm with good financial backing will always have a great advantage over a Government department with a strictly limited budget allowance for re-It says much, therefore, for the scientific search direction of the Admiralty of that time, that the Admiralty is to-day numbered among the pioneers of this great invention.

Wireless has been taken as a typical illustration. To the man in the street it represents simply an invention, a single invention and an apparently simple one represented by a small wooden box with a knob to turn. But to the scientific historian who tries to decipher all that the little box represents in human thought and effort, it presents an appearance of amazing complexity in which the discoveries and inventions of some of the finest brains of two centuries are inextricably blended.

#### INVENTION AS A HISTORICAL SCIENCE.

The science of invention is a curious blend of the exact sciences, like mathematics, physics, and chemistry, with a historical science. It is in many respects similar to the science of war, the war being against the complexity of Nature, man's ignorance of that complexity and the inefficiency and insufficiency of the human intellect itself.

Yet if we compare this contest with the wars of man with his fellow-man, what a difference we find. Napoleon said he learned the art of war from a study of the lives of the 'great captains,' but in the greater war with Nature, if we consult the books that have been written round the lives of its 'great captains,' we find only human documents in which the searcher after knowledge, to help him to carry the fight a little further, finds little help beyond an example of high courage. The technical difficulties are seldom recorded, and the new searcher has generally to start afresh and reconnoitre his way across the old battleground of centuries. The fault sometimes lies with the chronicler, but too often with the lack of records which the 'captain' might have left but

 $<sup>^{\</sup>rm t}$  From the presidential address delivered to Section G (Engineering) of the British Association at Leeds on Sept. 1.

failed to leave In fact, here we have a startling lesson from the science of war, for is it not drummed into every budding soldier until it becomes second nature when he attains command, that one of his first duties in the field which must never be neglected is to maintain communication and pass on all information that may come his way, whether it be useful to him or not? The lesson has two sides. The soldier knows that he may become a casualty at any moment and the information which he gleans may be of vital importance to enable some one else to carry on in his stead, also, that information which may appear unimportant to him may prove to be the key to the movements of the enemy elsewhere of which he is in entire ignorance

Of the hundreds of inventions which have been a and oned as failures, or of possibly revolutionary inventions left incomplete simply from lack of capital or lack of courage, no record is available to those who come after and might carry them on to success. Has every inventor for all time to start from scratch? The same difficulties crop up time after time in the development of inventions, yet every new inventor has to tackle the difficulties de novo, and fortunes are wasted in

the process.

Development of an invention is always costly. even when guided by all the experience obtainable from allied inventions, how much more costly it is when not so guided, the history of the failures would most surely show. In most inventions there comes a time when the inevitable question arises, 'Shall we cut our loss or risk further expenditure?' If the decision is to cut the loss, the invention, which is possibly a sound one and of great value, is pronounced to be a failure, and the result may be the loss of an industry to the country or a delay in its introduction for many years. Science will prevail in the long run, but the cost of the trials both in time and money could probably be greatly curtailed if records of similar ventures in the past were available. Invertors would gain much if they could be trained in, and benefit by, the experience of their predecessors in the same field, while masters of industry. with records of that experience before them, would be better able to appreciate the difficulties of the inventor and to co-operate fully with him.

In every industry one finds that the experience gained in developing the inventions of the industry is often guarded as a most valuable secret. The result is that this knowledge is not recorded and often dies with the individuals who possess it. Future workers even in the same industry have to pass through the same or similar experience to regain the lost knowledge and the whole condition is economically unsound. The expense to the nation which it entails must be enormous. It retards progress, it adds greatly to the time and expense of developing other inventions, and it brings invention into disrepute because so many firms have lost money in trying to develop inventions which have had to be abandoned simply through inexperience.

INVENTION AND INDUSTRY.

The history of the twentieth century shows clearly that invention is the heart of industry, the root of new developments, and the source of improved methods of production which have led to cheaper costs and a wider scope in every industry. It has also been the cause of some of the greatest social upheavals and strife. Innumerable strikes have arisen from it, and if there is one lesson in political science more potent than another to be learned from the history of such movements, it is that science is always victorious in the end. Progress may be delayed or an industry may be lost to a country temporarily or permanently by such strife, but the steady advance of the world's progress through the science of invention is certain. One country may lose, but the world will gain in It is only a question of time, and if the leaders of industry, both masters and men, would only recognise this fundamental truth, how much faster progress would be.

It must not be imagined, however, that every invention can or, from the commercial point of view, should be introduced into an industry the moment it is made. Quite apart from the time necessarily spent in developing and perfecting the invention, for which purpose many industries have now instituted research departments of incalculable value, it is sometimes found that the occasion is inappropriate or that the time is not ripe for the change involved The introduction of a new invention or of a new design may involve many complicated questions of policy or finance, because the change may have to be accompanied by heavy sacrifice in other directions, possibly affecting other industries or the public at large. There may have to be heavy scrapping of spare parts, There may also be considerable tools and plant loss to the customers of the industry through depreciation of the products of the industry already in use, for nothing depreciates a firm's production more rapidly than the introduction of

a new and superior model

Manufacturers have therefore, on some occasions, to collect and husband their inventions and improvements after testing their merits and keep them in reserve for a more opportune occasion. The opportunity may occur very suddenly. It may arise through a sudden whimsical change in fashion which no one can explain, or from some other cause which it has been impossible to anticipate, and if a manufacturer has no policy of improvement all worked out and ready to apply, he is faced with the awkward alternative of falling behind the times by making no change at all, or of risking his market by adopting some new model which he has not had sufficient time to test thoroughly. The former policy is almost always disastrous and the latter is often worse. Numerous illustrations of both these courses and their results could be cited from any industry. There inevitably comes to every industry a time when radical change is demanded, and the firm which is best prepared for the change reaps the reward of its foresight.

Industry when viewed in its international aspect determines the lives of nations. The nation which organises its industry most efficiently, which hampers it least and stimulates it most by legislation, or absence of legislation, and by its scientific foresight, is the nation which will prosper most. Since invention is the heart of industry, the inquirer naturally asks. Is this country doing its best to stimulate invention as a means to foster industry? Are the leaders of industry fully alive to the position which invention plays in industrial progress? Have our legislators ever paused to think that their functions are only called for because of the progress which has been made by scientific invention, and that without such progress they would be unnecessary; also that, in the past, legislation has done much to retard progress ? A study of the fundamental scientific causes of progress would form a useful addition to the education of legislators

#### INVENTION AS A LINK BETWEEN EXACT SCIENCES.

It is sometimes stated that the physics of to-day becomes the engineering of to-morrow. This is a natural development, since the engineer is more concerned than the physicist with the practical application of physical discoveries. But the converse is frequently true, for many physical discoveries and inventions arise from difficulties encountered by the engineer. The science of practical hydrodynamics is a case in point. The mathematical science of hydrodynamics has been of little service to the engineer in the practical problems of the propulsion of ships, in the complex phenomena of vortex motion associated with the flow of water and steam through turbines, or in problems of aerodynamics, with the result that the engineer has had to develop an empirical science of hydrodynamics to supply his immediate needs. A huge mass of experimental results in screw propulsion, in aerodynamics and in hydraulics has thus been accumulated and is now awaiting some discovery or discoveries in mathematics or physics to correlate it all. If vortices could only be dealt with like potatoes or any other form of merchandise, each a complicated physical system in itself but capable of being considered as a unit differing only in mass or in its energy contents, a forward step might be made. The Lanchester-Prandtl theory of lift and drift of aeroplanes is a first step in a particular case of the general problem. Such a discovery, when made, will be bound to lead to further advances and improvements on the engineering side of the subject.

Most discoveries in physics arise from some experimental fact discovered more or less accidentally. The discovery of Röntgen rays was accidental, and the enormous strides which have been made in our knowledge of the atom by J. J. Thomson, Rutherford, Bragg, Bohr, and many other physicists during the last thirty years have resulted from Rontgen's discovery combined with another great discovery in pure thermodynamics, Planck's quantum theory, which also arose from an accidental discovery made in the course of ex-

periment. The Reichsanstalt in Berlin had published a family of curves representing the distribution of energy in the spectrum of a hot black body. Prof. Wien by trial and error obtained an equation to the family, and the form of this equation was suggestive. Planck, in trying to develop this equation from the laws of thermodynamics, found that he could only do so by assuming that energy is not indefinitely divisible and he comed the term 'quantum' to represent the fundamental unit.

These two discoveries of Rontgen and Planck form the starting-point of that most important branch of modern physics which has increased our knowledge of the constitution of matter, a science which is just beginning to find its field of application in engineering practice, as in the thermionic valve and the modern power transformers on the same lines. From these and other applications

great advances are still to be expected.

In reviewing the discoveries in physics which have had most effect in developing new industries and thus calling forth new inventions, one is struck by the great results in this respect which have arisen from application of the second law of thermodynamies, first stated by Carnot in 1824. Carnot described his ideal heat engine and showed that the efficiency of this engine is independent of the working substance used. Looking back upon the history of the science of thermodynamics of the last century, it is unfortunate that no one seems to have employed this statement of Carnot's as a general text, and developed it to find what information could be derived from it by using different working substances and mixtures in order to discover something about all the substances used. Had any one done so, progress might have been greatly accelerated

James Thomson was the first to use this second law to determine the lowering of the freezing point of water due to pressure. His brother, Lord Kelvin, followed with the application to the change from liquid to vapour. Helmholtz used the voltaic cell as the working substance and determined the temperature coefficient of its electromotive force. Then followed at long intervals the applications to chemical changes which have resulted in the modern science of thermodynamic chemistry with which the names of Helmholtz, Ostwald, Nernst, Van't Hoff, and Gibbs are so closely associated, and upon which the modern industry of chemical

engineering is based.

It is a wonderful development to be able to prophesy that under certain conditions a certain chemical reaction will take place, say, that the nitrogen and oxygen of the air will combine at certain temperatures and pressures in a definite proportion, and that the resultant oxide can be recovered and converted to nitrate and used as fertiliser to replace the imported article at an economic price. The applications of thermodynamic chemistry to explosives enable us to calculate the maximum pressure to be obtained by detonating an explosive, or to calculate the temperatures and pressures throughout the ex-

plosion of cordite in a gun from the chemical constituents of the cordite. This possibility has gone far to raise internal ballistics from an empirical science to a branch of natural philosophy.

The advances which have taken place in the commercial development of chemical processes based upon this important new science of thermo-

chemistry, although already considerable, are only in their infancy, but the men with the experience gained in practical development are very few; and as the experiments are generally very lengthy and expensive, the development of the industry is necessarily slow. The resultant saving to the country, however, will far outweigh the cost.

(To be continued)

#### Indian Agricultural Practice and Research.

DURING the past century of British rule, many attempts have been made to improve Indian agriculture; but wave after wave of effort has broken, with little result, on the firm foundations of the indigenous practice of the country. Until within quite recent years, only in the fundamental matters of irrigation and reduction of famine has any notable advance been made. It is well, then, to look back and try to form a picture of the nature and origin of this indigenous agricultural practice.

When we do so, we are at once struck by the commanding position of the industry in former times, and the enthusiasm with which it was carried on It is generally agreed that the Aryans, an agricultural people, entered the north-western part of India some 4000 years ago; and the view is also held, although more conjecturally, that the Dravidians, also noted agriculturists, had then already intrenched themselves in the south. Of the latter we have little knowledge. But there is detailed evidence in the ancient writings of the delight with which the Aryans regarded cultivation-witness the following extracts from a pastoral hymn on ploughing in the Rig Veda (period 2000 to 1400 B.c.): "Let the god of rains moisten the earth with sweet rains . . . may the crops be sweet to us . . . turn the sod merrily, let the oxen work merrily, let the plough move on merrily, fasten the yoke merrily, apply the goad merrily." Allowing for a certain poetic exaltation, this was a bright beginning; and was undoubtedly followed by a great development of agricultural knowledge and practice in north India. There appears to have been steady progress at any rate until the early part of the Buddhist period (500 B.C. to AD. 500); and western knowledge of Indian agriculture dates from this period, in that it was carefully studied by the Greeks, shortly after Alexander the Great entered the country in 326 B.C.

In ancient India, soils were classified according to colour, taste, productivity, and suitability to particular crops; alkalinity was known and feared; irrigation was widely spread, by dams, tanks, and wells; methods of dry farming were practised; deep ploughing was universal; manuring with animal residues and with oil cakes was practised, and green manuring was known and valued; paddy was sown in nurseries and transplanted into puddled fields; most of the crops now grown were cultivated; the seasons and rains were well understood and allowed for, and agricultural practice seems to have reached a high

level 2 But after the peak was reached, there would appear to have set in a steady decline both in the enthusiasm for agriculture and in the importance attached to it. Most of the details have, however, been handed down by example and oral tradition to the present day. But an Indian writer, after discussing these ancient glories and the progress being made elsewhere, allows himself to describe the Indian cultivator as "an ignorant, custom-bound creature, forced to content himself with his lot." Naturally, the inquiring western student will not altogether agree with this; rather is he struck by the wealth of detail, the rare economy, and the surprising adaptation to environment, and he soon discovers in that environment the main reason why Indian agricultural practice appears to be a mass of contradictions, when first viewed by those trained in western scientific methods.

Putting it briefly, the work of the Indian cultivator is often excellent, considering the limits of his conditions and resources. The first business of any one desiring to improve matters must be a study of this environment. The important benefit conferred by British rule in the development of irrigation has been already referred to; the next great advance was made when, in the early years of the present century, the Government at last recognised the necessity of founding an adequate agricultural department and allocating funds for its permanence. This was done on a generous scale by Lord Curzon, and during the past quarter of a century this department has been expanding and 'digging itself in'; in place of some half-dozen agricultural officers, nearly 200 superior posts have been created, and the number is daily increasing.

Defining research as the detailed study of any subject by a scientifically trained mind, the first difficulty of these officers was to bring their training into alignment with Indian conditions. Any attempt at betterment was of necessity dependent on a knowledge of the local climate, soils, stock, implements, crops, and the resources of the people. Amelioration or alteration was obviously needed, but a series of interlocking factors made this very difficult. Irrigation and dry farming had been practised from ancient times, but are always susceptible of improvement. There is plenty of good soil in India, but much of it has, by continual cropping without due return, reached the verge of 'permanent infertility.' There is a marked deficiency of pasture land, and what there is, is often very inferior; the cattle, therefore, although

<sup>&</sup>lt;sup>2</sup> G. Jogi Raju, Journal Madras Agricultural Students' Union, 8, 2-4, 1920.

numerous, are generally small and weak. As a consequence of this, agricultural implements have to be designed with an eye to the strength of the animals rather than the needs of the soil of humus and nitrogen content are characteristic of cultivated land in the tropics; and cattle manure is easily the most suitable material for remedying this. But most of this manure is, in India, of inferior quality and the bulk is used as fuel; while the rich nitrogenous residue from oil pressing is largely sent out of the country. Pure seed is practically unknown, a field of any crop being usually a mass of unselected varieties. Taking all these things together, the cultivator gets little out of the soil, it is not to be wondered at that he is poor, and anything like the accumulation of agricultural capital is out of the question. Without this capital it is difficult to see the way to any permanent improvement.

The principle of co-operation was early invoked, and some of the first agricultural successes were Agricultural largely dependent on its application co-operation has been an enormous success, and has spread through all the provinces, and it was long ago taken out of the hands of agricultural officers, with a department of its own century efforts have been made to improve the character of the crops grown, largely by introducing strains grown elsewhere; and one of the first lessons learnt in the new department was that this method was unlikely to succeed to any great extent, but that in the mixtures grown many forms were worth selecting and purifying. Work in this direction has been a great success in almost every crop studied, and some seven or eight million acres are now under selected strains of wheat, cotton, jute, and rice, while hybrid canes have been evolved which are rapidly replacing the former inferior kinds.

These two lines of work, co-operation and seed selection, are readily appreciated by the cultivators, and obviously place him in a better financial position. They may thus be regarded as laying the foundation for improvements in other directions. Meantime, a great deal of study was devoted to the pests and diseases of the crops grown, and means for their control worked out. Alterations in agricultural practice, because of its time - honoured nature, are much more difficult. It was soon seen that the importation of the costly and powerful implements of the West would be unsuitable in the circumstances; and as with the crops, a careful study was made of the local village equipment, costing a few shillings, on the chance of increasing its efficiency. Cheap models of improved ploughs, harrows, cultivators, etc., have been evolved; and some 30,000 of these are sold every year. But it must be confessed that a great deal more remains to be done.

There are some 150 million cattle in India, and this very number is one of the chief bars to their improvement in quality. Yet cattle may be said to represent the key factor influencing soil fertility and agricultural practice in India; and far too little research has been devoted to this difficult

problem. An excellent Vetermary Department has existed for years, but it is only quite lately that a proper liaison has been effected between it and the Agricultural Department. One of the most encouraging features of the present-day research is the increasing attention being paid to cattle questions.

Agricultural research in India has, in the past, lagged considerably behind that in Great Britain, for the simple reason that the number of trained men employed was so absurdly inadequate for the work. The total area of the Indian Empire is given as some 1100 million acres. Of this, British India covers a little more than half, the rest being under native rulers; about two-thirds of British India is classed as cultivable. Such figures are impressive; but no one can appreciate the situation as regards research on the agriculture of the country, who has not spent the best years of his life in odd corners endeavouring to better things, continually making long train journeys over territory as yet untouched. This must be constantly borne in mind when reading of the successes of which the Agricultural Department is so justifiably proud. It is probable that not one hundredth part of the country has as yet been

materially affected.

Taking the broad view, we may regard the efforts of the past quarter of a century as so much preparatory spade work; in almost every direction we know a great deal more about the crops and their environment, and can now form an opinion as to where progress may be reasonably expected. Encouraged by incidental successes along the path, the officers of the Agricultural Department are busy applying the most recent advances obtained elsewhere to the solution of their most pressing problems. It is only possible to refer here to one aspect of this development, namely, a fundamental study of the nutrition of man and beast under Indian conditions 3. Thus study embraces the whole of agriculture, as well as veterinary science and certain aspects of medicine. In each case the soil is the basis, with cattle, its mineral constitution and the effect of this on the pasture and vegetable food generally; and with man, the inherent nutritional value of the staple foods of the different nations, and the effect of soil treatment on the nutritive value of the different cereals eaten. The two studies are interlocking. For example, it has been found that the nutritive value of cereals is distinctly higher when the crop has been treated with cattle manure than when artificial manures were used. It is obvious that a great many years of work will be needed before either of these projects can yield its full results. But a promising start has been made. Some of the analyses have shown a surprising difference in the proportions of the more important vitamins in the different cereals; and experimental feeding of animals has thrown suggestive light on the known variation in virility and disease resistance of the different nations inhabiting India--work which will awake interest far beyond the limits of the Indian Empire.

#### Obstuary.

Prof W Burnside, F.R S.

BY the death of William Burnside, England has lost a mathematician of rare ability and lasting achievement, and his science can now inscribe another name on her bead-roll of memorable men.

Burnside was born on July 2, 1852, the son of William Burnside, a merchant, of 7 Howley Place, On the paternal side, the ancestry was Scottish: his great-grandfather had been minister of St. Michael's in Dumfries His grandfather went to London and, in the earlier half of the last century, was a partner in the bookselling and publishing firm of Seeley and Burnside

Left an orphan at the age of six, Burnside was educated at Christ's Hospital, where he was a Grecian—a privileged dignity which, by those who know it not, may be pictured from Lamb's essay on that ancient foundation At the school, Burnside attained pre-emmence in mathematics as well

as in grammar

He was elected 1 to an entrance scholarship at St. John's College, Cambridge, being the first man of his year—in the old phrase; and he went into residence in October 1871. Late in his second year (May 1873) he migrated to Pembroke College in the same University. Hegraduated in the Mathematical Tripos of 1875 as second wrangler, being bracketed with Chrystal, who afterwards was professor at Edinburgh; and in the subsequent Smith's Prize examination, Burnside was first, Chrystal second.

A fellowship at Pembroke followed, in his Tripos year. he continued a fellow until 1886. He was at once appointed to lecture in his college: and he lectured also at Emmanuel in 1876, and at King's in 1877. College teaching included selections from the normal course for the Tripos; and Burnside also gave lectures, in one advanced set open to the University, on hydrodynamics subject was coming into vogue again at Cambridge: attention, regularly paid to the previous work of Stokes, was stimulated by the then new work of Greenhill and of Lamb Burnside examined for the Tripos from time to time; and occasionally he did some private coaching.

In one respect, however, Burnside maintained a special undergraduate interest. indeed, a vigorous youthfulness of bearing and appearance was a characteristic through life. At St John's, even as a freshman, he had rowed in the Lady Margaret Eirst Boat which, with the famous Goldie as stroke, went head of the river in 1872 a success not repeated until 1926 Rather light in weight when an undergraduate, always spare and enduring, he kept his rowing form for many years. He rowed in the Pembroke boat so long as he remained in residence after his graduation: a splendid '7,' he had a full share in its steady rise on the river. For some years after he left Cambridge, his reputation as an oar was a tradition in college circles.

<sup>1</sup> For several of the personal records, the writer is indebted to the present Master of St. John's College, Sir Robert F. Scott, who was fourth wrangler in Burnside's year.

After going out of residence, such opportunities for rowing were no longer open. But Burnside had acquired a zest for fishing, and had often gone to Scotland he continued to go there, many a summer, to pursue what grew to be his favourite sport He became an expert fisherman. There were no half-measures with Burnside in any occupation: whatever he undertook, he did thoroughly.

In 1885, at the instance of Mr (afterwards Sir) William Niven, the Director of Naval Instruction himself an old Cambridge man, devoted to natural philosophy, as it was styled—Burnside was appointed professor of mathematics in the Royal Naval College at Greenwich. The rest of his teaching life was spent there. There was a current belief that his old college, Pembroke, had invited him to return to important office. But he remained at Greenwich: his work was to his liking: and the multifarious detail, incident to the duties of a college office or of the presidency of a scientific society, such as the London Mathematical, was almost mexpressibly irksome to him through all

the vears At Greenwich, Burnside's work was concerned with the training of naval officers. It consisted of three ranges There was a jumor section for gunnery and torpedo officers, the chief subject being the principles of ballistics. There was a senior section for engineer officers, the chief subjects being strength of materials, dynamics, and the like. The advanced section-perhaps that in which he exercised the greatest influence on his students—was for the class of naval constructors there, his special mastery of kinetics and of hydrodynamics proved invaluable. He was a fine teacher, stimulating, patient with students though, elsewhere, occasionally his manner might have a note of abruptness he certainly earned their gratitude, as appeared from their spontaneous token of tribute to him when he left in 1919, in an address treasured by him and his family

Burnside had married Alexandrina Urquhart in 1886, soon after going to Greenwich: she survives him, with their family of two sons and three daughters. After his work at the Naval College had ended, they retired to West Wickham in Kent; he enjoyed a leisure spent among his continued researches, his books, and in fishing holidays up in the north. The last year of his life was marked by failing health: and the proximate cause of his death was a recurrence of cerebral hæmorrhage. He died on Aug 21 last: and he is buried in West Wickham churchyard.

Valuable as was his teaching, important as was his influence alike as an examiner in the highest ranges of mathematics and as a strong referee upon contributions submitted to learned societies, it is by his own contributions to the mathematics he loved that Burnside's name will be held in remembrance

Throughout Burnside's residence at Cambridge,

the University had been in the finest flower of her activity in applied mathematics Stokes, Cayley, and Adams were the long-established professors: Maxwell's appointment had been more recent. Physical astronomy, dynamics, light, sound, heat, were the staple subjects of the best students range of electricity and magnetism, except for an infusion of some of the work of Sir William Thomson (afterwards Lord Kelvm), was rather Maxwell's presentation had still to make its place in the Cambridge course, men scarcely even dreaming of the revolution it was to accomplish. Pure mathematics (save for the exceptional appearance of a Clifford or a Glaisher) was left to the unfrequented domain of Cayley. Much of the original thought of her mathematicians in those years found its expression in Tripos problems, a veritable mine of isolated results propounded as Senate House conundrums. Even so, the worship of the mathematical spirit at the shrine of natural philosophy was maintained in a distinctly conservative range. At the beginning of his work, Burnside could scarcely fail to conform to the Cambridge use: indeed, as regards activity in applied mathematics, he largely remained in the older round to the end.

Burnside's earliest lectures were devoted to hydrodynamics, as has been stated already. But the old-fashioned methods for conjugate functions, stream-lines, velocity potential, were being analytically transformed through the introduction of functions of the complex variable For many a day Cambridge had preserved an almost invincible repulsion to the then objectionable  $\sqrt{-1}$ , cumbrous devices being adopted to avoid its occurrence. But some teachers could show that, in twodimensional fluid motion, simplicity and new results were easily attainable by its means; and its formal Cambridge debut was made in Lamb's book. To Burnside's intellect, the new calculus appealed: and, as a matter of record, his first published paper is concerned with elliptic functions, not with hydrodynamics. That paper, modest in size, finished ('elegant' was a favourite epithet) in quality, was published in 1883, and thereafter there flowed a swelling current of papers, embodying the thought of his active brain.

It is not difficult to note various stages in the progress of Burnside's knowledge. From time to time there is an occasional return to his earlier preferences. Thus he had produced hydrodynamical papers in the early 'eighties: he returned to the discussion of waves in 1914. The 'potential,' as used by Green, by Stokes, by Thomson and Tait, was all-important in the Cambridge of the 'seventies: Burnside wrote a paper on that topic in 1894, but the work was now beginning to be affected by function-theory. It soon appeared that he had wandered far from his ancient fold. He had made a profound study of the newer (Weierstrass) elliptic functions, proved in the quality of a few scattered papers. He had delved into differential geometry, a subject which was ignored in Cambridge except for some rarely read selections in Salmon's "Geometry of Three

Dimensions "His study of elliptic functions had compelled him to range - he always ranged to purpose—in the field of the general theory of functions.

Burnside's matured development flashed out me his two papers on automorphic functions, written in 1891 and 1892 The subject belonged to a new section of knowledge, largely maugurated by Henri Pomearé, whose exposition was contained in a succession of memoirs, now classical, in the initial volumes of Acta Mathematica. The underlying idea is simple. Trigonometrical functions are singly periodic: that is, they repeat <sup>2</sup> their analytical form and values, when the argument suffers an increment or a decrement which is any integer multiple of a single quantity. Elliptic functions are doubly periodic: that is, the repetition of form and values occurs, when the argument is similarly changed by integer multiples of two distinct quantities whose ratio must not be real. Jacobi had proved, long ago, that triply periodic uniform functions of a single argument do not exist. But the question remained (though even the existence of such a question had not been obvious, until it was propounded): What is the most general type of periodicity for a function of one variable? And then, naturally, there followed the question: What are the functions with that type of periodicity? Isolated results were known, though of unrealised significance, indicating a general theory, such as Jacobi's elliptic modular functions, and Klem's icosahedral functions. But it was Pomearé who presented the first systematic consideration of the questions.

Into this work of Poincaré, Burnside plunged; in it he revelled; and his fundamental results are to be found in the two papers already mentioned. They have the finished character usual in his work: terse, tree from digression ("No flowers" might have been his motto), moving swiftly in their advance to new results, they reveal the power and the knowledge of a master. In particular, Poincaré had overstated an exclusive result: Burnside detected the overstatement and the cause: and he devised a new class of such functions, simpler than any of the classes due to Poincaré. This investigation led to both simplication and to advance. The full theory has yet to be completed: it awaits the construction of a central function or functions which, while palpably automorphic, shall submit to the customary analytical manipulations, as do the corresponding theta-functions of purely incremental periodicity. When the history of the written, Burnside's name will theory comes to hold an honourable place in the record.

The correction of the very foundation of these artomorphic functions led Burnside further afield, into a region where he explored with ample result. For every such function, the argument is subject to a number of operations, which are independent of one another, are capable of unlimited repetition, and admit all possible combina-

<sup>&</sup>lt;sup>2</sup> The writer remembers one day when Sir William Thomson surprised his hostess at lunch by asking her whether she had noticed that "all the carpets of Christendom are strictly periodic."

ons and repetitions in unrestricted sequence. The aggregate of all the operations, which thus emerge, is termed a group, so that a function is automorphic under a group of transformations But just as the properties of the integers, which occur in the arithmetic of any calculation, merge into the general theory of number without regard to any specific application, so the properties of a group of transformations of an automorphic function are but a part of a more comprehensive calculus. That calculus deals with the composition, the construction, and the resolution, and the essential properties of a group, regarded as an abstract entity subject to mathematical laws, and without any consideration of the regions of its use, whether they are algebraic equations, or analytic functions, or differential equations, or rotations of a solid body, or the divisions of space, to mention only some instances. The first expression of the general notion was due to Galois later, it found a fine exponent in Camille Jordan. By the late 'sixties it had secured mereasing attention in the continental Schools, where soon it divided into two co-ordinate theories, continuous groups and discontinuous groups. The former theory became a grand body of growing knowledge under the inspired researches of Sophus Lie

It was to the theory of discontinuous groups that Burnside devoted himself in the main, though he attained a stage in the discussion of their invariants where some processes of the theory of continuous groups may yet be drafted into service. Paper after paper appeared from him, on a variety of issues, in ordered development, ever adding fresh contributions to the theory, and marked, all of them, by imaginative vision and compelling power. They found their first culmination in his book on the "Theory of Groups," published in 1897, a systematic and continuous exposition of the subject as it then stood, embodying researches of continental workers (always with ample references) as well as his own. His production of papers, on the theory of groups, continued unhastingly and unrestingly; and the range of the second edition of the book, in 1909, was considerably greater than that of the original volume. Even so, his activity in the subject still continued, though with a gradually decreasing production. All this work, original from himself and copious in extent, is a splendid contribution, emanating from one mind, and sufficient to secure the remembrance of his name.

With the coming of the War, there was comparative cessation in Burnside's work. His frame was almost as lithe as ever and apparently as full of easy spring, seeming to belie the passage of years: but his constructive activity in published mathematics slackened, some of it passing silently into the service of his country, in certain naval matters. In those years he undoubtedly continued to produce papers; but the main body of his creative work might be regarded as verging towards its termination.

There stands, however, in the list of Burnside's memoirs, one brief paper (dated 1918) dealing with a topic in probability, among its fellows, it seems

strangely isolated. It now appears that his thought had been settling towards that subject for some time. He has left a draft, which could have been developed into a treatise, on probability though only consisting of the initial chapters, it is complete within its range, it will make a small volume which can proceed to publication exactly as it was written

In recognition of his eminence as a mathematician, not a few academic honours came to Burnside in life He received honorary degrees, Sc D. from Dublin, LL D from Edinburgh He was elected a fellow of the Royal Society in 1893, served on the Council of that body in 1901 and 1902, and was awarded one of the two Royal Medals in 1904 He was a member of the Council of the London Mathematical Society for the long continuous period from 1899 to 1917, where he was a tower of strength in advice, he was awarded the De Morgan medal in 1899: and in 1906-7-8 he served as president (he had accepted the office with grave and characteristic reluctance) honour which he esteemed perhaps most of all, was conferred on him in 1900 he was then elected an honorary fellow of his old college, Pembroke, of which he had become the senior among the honorary fellows at the time of his death Yet even in the few remarks of thanks which he made at the College dinner welcoming, by courteous custom, the newly elected honorary members of the foundation, he urged that the happy and successful pursuit of research was its own reward; and the sincerity of his plea was appreciated not least by those who had done their part in recognition of his labours.

Significant and merited as were the academic honours conferred upon him in life, to William Burnside, as to men of like mark in their generations, the most enduring monument is the work that his genius contributed to the progress of his science

A. R. F.

#### MR. C. M. WOODFORD, CMG.

WE regret to record the death at Steyning, Sussex, on Oct 4, of Mr Charles Morris Woodford, for eighteen years administrator of the Solomon Islands. Mr. Woodford was born at Gravesend in 1852, and educated at Tonbridge School. On leaving in 1871, he went to the western Pacific as a naturalist and collector for the Rothschild Museum at Tring. For ten years he explored Melanesia, visiting the Solomons three times between 1886 and 1888. These islands then had few European inhabitants. Most of them were British, and they lived in constant danger from the native inhabitants, whose habits then fully accorded with the popular idea of a savage, as they were bloodthirsty cannibals, and assiduous in headhunting Woodford, however, succeeded in acquiring a considerable knowledge of their habits and characteristics, which he was afterwards to turn to good use

In 1895, Mr Woodford became acting Consul and Deputy Commissioner in Samoa, and in the following year he was appointed first resident

Commissioner in the Solomon Islands by Sir J. B Thurston, Governor of Fiji—In 1900 he proclaimed the Solomons a British Protectorate and hoisted the flag. In 1912 he was made a C.M (), and in 1915 he retired. During his term of office he succeeded in impressing his strong personality on the natives. He induced them to abandon their head-hunting and cannibalistic habits, and put down the murder of white traders and missionaries—Under his influence the natives provided the labour for the extensive coconut plantations established in the comparatively settled conditions which he set up, even though sporadic outrages, such as that reported within a day or two of his death, still occurred.

Mr. Woodford's profound knowledge of the natives was mainly turned to profit in the practical affairs of administration; but such contributions as he made to anthropological literature were

marked by their powers of close observation and careful and accurate record

WE regret to announce the following deaths:

Prof. Max von Gruber, president of the Bavarian Academy of Sciences, known for his work on social hygiene, on Sept. 17, aged seventy-four years.

Lord Iveagh, K.P., G.C.V.O., F.R.S., Chancellor of the University of Dublin, who, among numerous public benefactions, gave £250,000 to the Lister Institute of Preventive Medicine for the endowment of bacterological research, and was elected in 1906 to the Royal Society under Rule 12, which provides for the election by the Council of "persons who, in their opinion, . . . have rendered conspicuous service to the cause of science," on Oct. 7, aged seventy-nine years.

Prof. Emil Zettnow, director of the department of photomicrography at the Robert Koch Institute in Berlin, on Sept. 7, aged eighty-five years.

#### News and Views.

In an article in last week's issue of Nature, the main characteristics of several types of metallurgical photomicrographic apparatus at present on the market were discussed, and it was suggested that British manufacturers must pay more attention to details of mechanical construction and design of this type of apparatus if they are to compete successfully with Continental manufacturers. That such competition is making itself felt is shown by the fact that twentytwo institutions and firms in Great Britain, and also sixteen in the United States, have recently installed Reichert metallurgical photomicrographic equipments of the type referred to in the article. From the point of view of British industry, it is unsatisfactory that so many British purchasers should have to place their orders with a foreign firm for an apparatus of such importance in industry and in scientific investigations. In 1920 the Faraday Society, under the presidency of Sir Robert Hadfield, in conjunction with the Royal Microscopical Society, the Optical Society, and the Photomicrographic Society, held a symposium on "The Microscope: Its Design, Construction, and Applications." A valuable discussion took place, in which microscope users stated their requirements and manufacturers presented their proposals to meet these requirements. The meetings aroused a considerable amount of enthusiasm on the part of manufacturers and resulted in the production of several types of microscopes of such a quality and m such quantity as to meet fully the requirements and the demands of the users. It would seem, however, that in regard to photomicrographic apparatus for metallurgy, the manufacturers have not kept pace with the demands of the metallurgists.

MESSRS. Hadfield's, Ltd, desire to purchase an up-to-date metallurgical photomicrographic outfit. In order to avoid the necessity of placing the order abroad, Sir Robert Hadfield informs us that he or his firm is prepared to pay to any manufacturer who will supply a British-made equipment similar to the Reichert large photomicrographic apparatus, or one which fulfils the requirements of the metallurgist at

least as fully as does the Reichert, a premium of £50 in addition to the price at which the Reichert equipment is now obtainable. For photomicrographic work, the adjustment of the intensity of illumination requires a system of auxiliary lenses and light filters. These must be held in definite relation to the microscope itself, as must also the camera. For metallurgical purposes, the camera must be capable of being used also for macrophotographic work. This involves the production of an elaborate and delicate piece of apparatus, but it is certainly not beyond the resources of British microscope manufacturers. They have the advantage of a Scientific Instrument Research Association which is rendering valuable service to the industry. There is also a chair of instrument design at the Imperial College of Science and Technology, where the scientific principles of design are taught. The technical knowledge and skill of the British optician and mechanician are of a high standard, as is evidenced by several other types of instrument at present on the market. Since attention has now been directed to mechanical details in British photomicrographic apparatus in which improvement might be effected, it may be confidently anticipated that Sir Robert Hadfield's offer will meet with a ready response. Its acceptance and the successful completion of the order would undoubtedly result in increased sales of Britishmade apparatus of this type.

On Oct. 10, Prof. W. C. Melntosh, of St. Andrews, the Nestor of marine biology in Great Britain, entered upon his ninetieth year. Prof. E. E. Prince, Dominion Commissioner of Fisheries for Canada, who is visiting England, has sent us an appreciation of Prof. McIntosh's work, from which we are glad to print the following extracts. Born in St. Andrews in 1838, Prof. McIntosh passed through his arts course in the University of St. Andrews and his medical course at the University of Edinburgh. On graduating M.D. he was awarded the University gold medal, for a thesis on some peculiar features in the shore crab. Though burdened with heavy official duties when appointed to the Perth Mental Hospital in the late

fifties, he decided to devote himself as a scientific investigator to the marine annelids. The great "Monograph of British Annelids," the last of the long succession of superbly illustrated parts of which was issued only in 1923, is a monumental work. It will ensure lasting fame for its venerable author, and rank him as one of the very great zoologists of our time. The Nemerteans, so rich in the rock-pools of St. Andrews, first claimed his attention. At Perth, in sea-water tanks far from the sea, he skilfully carried on his studies on the living forms, and with marvellous artistic skill portrayed the gorgeously tinted creatures In 1884 was published the famous Report to the Royal Commission on Trawling, embodying work done on many cruises and including the discovery that the sole and other fish produced floating eggs. Prof. McIntosh is the pioneer in Great Britam of sea-fishery investigations, and it is a matter for congratulation that he continues active in the pursuit of zoological science and is as zealous as in his earlier years.

AT the opening of the thirty-sixth session of the School of Pharmacy of the Pharmaceutical Society on Oct. 5, the Hanbury Memorial Medal for "high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs" was presented to Dr T. A. Henry, Director of the Wellcome Chemical Research Laboratories Dr. Henry, in an address on receiving the medal, stressed the importance of maintaining a close relationship between pharmacology and organic chemistry. Although the position of Great Britain as a producer of new synthetic drugs has improved since 1914, yet it is only too notorious that many of the additions to the physician's armamentarium come from abroad, especially in the case of drugs used in the treatment of tropical diseases. This is not a creditable state of things for a great Empire: in part it is no doubt due to the fact that, as a nation, we are more interested in the preventive than in the curative side of medicine: on the other hand, the tack of facilities for pharmacological testing has also militated against research. For this reason, Dr. Henry welcomed the opening of a pharmacological laboratory by the Society. New compounds are always being synthesised, the pharmacological properties of which ought to be tested, especially when it is remembered that it is only one out of many examined, which will finally find its place in practical therapeuties. For scientific research, therefore, adequate facilities for pharmacological testing are essential, in order to direct the chemical work as it develops and to assist it as required. Moreover, quite apart from the production of new synthetic drugs, pharmacological assay of therapeutic substances of unknown chemical constitution, such as insulin, require the assistance of trained pharmacologists. In both these directions Dr. Henry considers that the new laboratory will prove itself of great value.

 $T_{\rm H\,E}$  presentation of the Hanbury gold medal of the Pharmaceutical Society of Great Britain to Dr. T. A. Henry, affords an opportunity for recalling

the work of the man whose name is commemorated in the name of the medal. Daniel Hanbury was the son of Daniel Bell Hanbury, a president of the Pharmaceutical Society and one of the founders of the historic business which still bears his name. The son, born in 1825, early impressed his contemporaries by the beauty of his handwriting and his skill at watercolour painting, talents which he later developed in his characteristically painstaking and detailed descriptive work. His writings included a series of papers on Chinese materia medica; numerous contributions to the Transactions of the Linnean Society, and the "Pharmacographia" published in conjunction with Prof. Fluckiger, of Strasbourg, which was completed in 1874. Shortly after his death in 1875, a fund was raised for the purpose of giving from time to time a gold medal to perpetuate his memory The medal is awarded for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs, the award being made by a committee composed of the presidents for the time being of the Chemical, Linnean, and Pharmaceutical Societies, the chairman of the British Pharmaceutical Conference, and one pharmaceutical chemist. Twenty-one awards have been made since 1881, when the first medal was presented to Hanbury's co-worker, Fluckiger. Englishmen naturally head the list of recipients, but Germany, France, Switzerland, Russia, and the United States are also represented The last award was made in 1922 to Prof. Emile Perrot, of the University of Paris, and in the list of earlier recipients occur the names of Dragendorft. De Vrij, Ladenburg, Tschirch, and F. B. Power. Dr. Henry's work has been mainly upon problems connected with the chemistry rather than the natural history of drugs, but his reputation in that field of research and the wide range of subjects covered in his published papers both in Great Britain and abroad, indicates the appropriateness of the award of the medal to him this year.

CONTROVERSY still rages over Glozel, and Dr. Morlet continues to champion the genuine character and the high antiquity of the alleged implements and inscriptions on the clay tablets found there in the Mercure de France and numerous separately issued pamphlets. In the meantime, according to a dispatch from Paris which appeared in the Times of Oct. 6, the site at Glozel has been declared a national historical monument, and M. Heriot, acting in his capacity of Minister of Education, has informed Dr. Morlet in a letter that it has been placed under the control of M. Peyrony, the eminent archæologist and member of the Historical Commission. M. Peyrony will be assisted by M. Champion, head of the technical department of the National Museum. All future discoveries will theretore be officially scheduled. M. Peyrony's profound and intimate acquaintance with the palæolithic sites of France and their antiquities should provide an acid test of the genuineness of any future find as Glozel. At the same time, it must be admitted that the camp of the pro-Glozelists is by no means negligible, including as it does Dr. S. Reinach, Dr. Van Gennep, M. de Laborde, Senor Leite de Vasconcellos, and Prof.

Mendes-Correa. They are, however, by no means While Dr Morlet regards the united in their views site as a link between paleolithic and neolithic, others, accepting the antiquity of the specimens, assign them to the various periods from the Magdalenian to the neolithic, but are hard put to it to explain the simultaneous occurrence of remains of all these periods on one site. Some, again, assign the site to so late a period as the Gallo-Roman. Against these views must be set the weighty authority of the Abbé Breuil and others, to which we have referred from time to time in these columns. Their great experience in handling the relics of early man renders their verdict of forgery one which it is difficult not to accept.

A Science Exhibition held at Hastings in the White Rock Pavilion on Oct. 5-8 shows what it is possible to do in popularising science among the inhabitants of a residential town. The promoters were local scientific and professional men, with the Mayor as chairman and the master of the Grammar School as honorary secretary and treasurer; in fact, it was quite a co-operative effort. The ann was to attract the ordinary man as well as the serious student by exhibits showing the advances in modern scientific knowledge, but the merely amusing was excluded This involved much thought in planning, but the actual getting together of models and apparatus did not present serious difficulty for, as the catalogue shows, they were obtained on loan from public institutions, firms, and private individuals. exhibits were divided into sections: engineering, electrical; radio and signalling; chemical and physical; and applications of science to the arts and to music. Since science objects, unlike art exhibits, cannot be appreciated merely through the eye, but call for exposition, care was taken to have stewards at hand to give explanations, while short talks and demonstrations followed one another from 3 P.M. until 9 P.M. each day; there was also a lantern lecture each day by a well-known man. The exhibition, which was well advertised by a specially designed poster and folder, was a great success, and may well serve to induce other local authorities to arrange exhibitions of a like character.

THE courses of lectures at the Royal Institution during November and December will commence on Tuesday, Nov. 1, at 5.15 P.M., with the annual course of three Tyndall Lectures, which will be delivered by Sir John Herbert Parsons on the subject of light and sight. These will be followed on Nov. 22 by four lectures by Sir William Bragg on a year's work in X-ray crystal analysis. On Thursday afternoons, beginning on Nov. 3, there will be two lectures by Mr. H. Clifford Smith on the furniture and equipment of the medieval house; three by Dr. R. E. Mortimer Wheeler on London before the Norman conquest; and two by Mr. James Kewley on petroleum natural gases and their derivatives. The Saturday lectures will be given at three o'clock, starting on Nov. 5, when Mr. Emile Cammaerts will give two lectures on the main features of modern English literature, to be followed by three musically illustrated lectures by Mr. Gustav Holst on Samuel Wesley and Robert Poarsall, and two lectures by Mr. F. J. M. Stratton on recent developments in astrophysics. The 102nd course of Christmas Lectures for Juveniles will be delivered by Prof. E. N. da C. Andrade on "Engines," commencing on Thursday, Dec. 29, at three o'clock. The subjects of the lectures will be (1) The rules which all engines must obey; (2) learning about steam; (3) engines which work to and fro; (4) engines which work round and round; (5) putting the furnace in the cylinder; (6) heat engines which produce cold.

Referring to the letter by Messrs. Rosenheim and Webster in Nature of Sept. 24, p. 440, Mr. C. A Hill, of the British Drug Houses, Ltd., writes informing us that, immediately after the publication of Rosenheim and Webster's work on ergosterol in February last, his firm placed irradiated ergosterol at the disposal of medical men. Since then, the British Drug Houses, Ltd., has achieved the largescale production of ergosterol and of the irradiated product, so that the latter is now available commercially. It is already on the market in a popular form for the public use; it is available for manufacturers of margarine to bring their product up to the standard of summer butter, which they can do at a fractional merease in cost, and chocolate manufacturers are already experimenting with it.

On Sept. 10 the second Pan-Union Archaeological Conference was opened at Sevastopol. It lasted until Sept. 15 and was followed by an excursion, in the course of which the delegates were conducted to the principal archaeological sites in the Crimea by Prof. C. E. Grinevich. The Congress coincided with the hundredth anniversary of archaeological excavation in the Chersonese, for, as stated in a historical survey by Prof. Grinevich, it was in 1827 that Admiral A. S. Greig, who was of Scottish descent, ordered Lieutenant Crusoe to begin exeavations in the Tauric Chersonese. Work was sarried on intermittently until 1885, when systematic excavation of this Dorian colony was begun and pursued continuously until 1915. It was renewed after the War in 1925, and at the same time the rich collections were reclassified and housed in the former monastery buildings. Representatives of the Academy of Sciences and the principal archeological museums and institutions of the Soviet Republics were present at the Congress, and a number of communications, some twenty in all, were presented in two sections, one covering Chersonese archæology, the other general archæology. Among these, G. A. Bonch - Osmolovsky described excavations in Kukrek and the Siuren Caves of sites belonging to the Stone and Bronze Ages, from which had been obtained bones of mammoth, rhinoceros, cave bear, and the skeleton of a dog. Considerable discussion was aroused by Prof. Grinevich's communication on the oldest defence wall of Chersonese, delivered from the wall itself, which seriously modified pre-existing ideas of the topography of the town.

TEE Imperial Department of Agriculture in India has commenced the issue of a new quarterly agri-

adtural journel, of which Part 2 (July 1927) has been received. The Journal of the Central Bureau for Animal Husbandry and Dairying in India, as it is named, will deal with cattle breeding, dairying, cultivation and storage of fodder crops, animal nutrition, and other aspects of animal husbandry, and the present number contains five articles on various aspects of Indian cattle and dairying, one on poultry feeding, and part 2 of a veterinary entoinology for India. The journal is illustrated and the subscription price is Rs 2-8 per annum.

The annual Report for 1926 of the International Health Board, Rockefeller Foundation, has been issued. Public health work has been assisted in eighty-eight States and countries. Governments have been assisted in surveys relating to yellow fever, hookworm, malaria, and other diseases, in campaigns for the control of yellow fever and hookworm disease, in field studies in malaria and hookworm disease and in demonstrations of malaria control; in county and district health work; and in the development of public health services, such as epidemiology and vital statistics, samtary engineering, public - health laboratories, and nursing. Contributions have been made to schools of hygiene for education, including the London School of Hygiene and Tropical Medicine. Fellowships in public health were provided for 253 men and women of thirty-one countries. The Board also co-operated with the Health Section of the League of Nations. The expenditure for the year amounted to 3,260,524 dollars The report gives a summary of the Board's activities and contains many maps, charts, and diagrams, and illustrations.

An air survey of the western part of Northern Rhodesia is to be undertaken by the Government of that country. The Times reports that the area to be surveyed covers the valley of the Upper Zambezi for about four hundred miles above Livingstone and includes the two tributary rivers, the Lungwebungu and the Kabompo. This region is almost entirely unmapped and undeveloped, but is believed to have considerable mineral wealth. Major Cochran-Patrick will be in charge of the survey and the aeroplane will be supplied by the Aircraft Operating Company. The machine to be used is at present working on survey near N'Changa, and will be flown to Livingstone to be fitted with floats. The aeroplane will fly at a height of 10,000 feet along the course of the river, and a series of vertical overlapping photographs will be taken. Larger scale photographs will be taken of rapids. Ground control is being provided by the company's surveyors, who will fix points by observation, using radio time signals.

ONE of the whalers at work in the waters around Graham Land is reported in the Geographical Journal for September to have made a voyage through Bransfield Strait and to have reached Peter I. Island, which has not been visited since its discovery by Bellingshausen in 1821. The whaler, Odd I., circumnavigated the island seeking in vain for a safe harbour; heavy weather prevented a landing. The island is

8 miles long and 5 miles broad Most of it is covered by snow or ice, and only on the western side is there much bare rock. It rises to about four thousand teet, and the absence of an ice foot on the coast suggests, but does not prove, that it is clear of solid pack throughout the year. The same whaler reports in lat. 60° 30′ S., long. 52° W., that is, west of the South Orkneys, an iceberg which was estimated to be about a hundred miles in length and 100 to 130 feet above the water line. Other enormous tabular bergs were sighted in the vicinity. It seems not improbable that these bergs represent the broken Stancomb Wills ice tongue of Coats Land or fragments The currents of the Wilhelm Barrier farther south of the Weddell Sea would carry ice from that direction to the north-western corner of the sea.

THE experiments being made with short radio waves all over the world are giving most astonishing results. In the October number of Experimental Wireless, the Radio Research Board refers to results obtained by E. Quack, published in two German technical papers. Oscillographic records have been obtained at Geltow, near Berlin, of signals sent from Rio de Janeiro. Each signal is accompanied by an 'echo' signal, caused most probably by waves which have travelled round the earth in the opposite direction to the direct signal. This is most curious, because the beam transmitter is not only directional but also works with a reflector. Further experiments carried out recently show that several signals are received at definite equal intervals after the first signal. As the interval of time between the first direct signal and these additional signals is always a multiple of 0·137 of a second, it looks as if the waves, after eausing the first signal, travelled completely round the world several times, recording signals as they passed the receiver. For waves lying between 14 and 34 metres, double signals have been observed. It has also been noticed that double signals occur most commonly when the great circle on which the receiver and transmitter lie is in twilight. On the other hand, the 'echo' signals caused by waves travelling round the world in the opposite direction to the direct signal are often noticed in the day-time. The attenuation of the signals after encircling the earth several times is not great, and it is concluded that many more encirclings occur before the waves subside. In practical work, methods have to be devised to eliminate the disturbances caused by these multiple signals, but their systematic study should be a great help in elucidating the phenomena of short wave propagation.

DR. W. G. SAVAGE, Medical Officer of Health, Somerset, will deliver the second annual Malcolm Morris Memorial Lecture under the auspices of the Chadwick Trust on Oct. 17. taking as his subject "Food Poisoning." The lecture will be given in the Hastings Hall of the British Medical Association.

The Council of The Institution of Civil Engineers has made the following awards: The Howard Quinquennial Prize to Prof. W. E. Dalby, in recognition of his researches on the strength and structure of

iron and steel; The Indian Premium to Mr. A. W. Stonebridge. For selected engineering papers published during session 1926–27: A Telford Gold Medal to Sir E. Owen Williams (London), Telford Premiums to Dr. E. H. Salmon (London), Mr. R. S. Cole (India), Dr. H. Mawson (Liverpool), and Mr. A. H. Douglas (London), and a Crampton Prize to Mr. D. M'Lellan (Glasgow).

APPLICATIONS are invited for the following appointments, on or before the dates mentioned. Three examiners (men or women) in the Industrial and Commercial Property Registration Office of the Mmistry of Industry and Commerce, Dublin, for the examination of applications for patents for mechanical engineering, electrical engineering, and chemical inventions—The Secretary, Civil Service Commission, 33 St. Stephen's Green, Dublin (Oct. 19). An assistant lecturer in agriculture, book-keeping, and farm costs at the South-Eastern Agricultural College, Wye - The Secretary, South-Eastern Agricultural College, Wye, Kent (Oct. 21). A fishing mate and a chief engineer in the fishery research vessel of the Ministry of Agriculture and Fisheries at Lowestoft-The Secretary. Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Oct. 22). An assistant naturalist in the Laboratory of the Marine Biological Association of the

United Kingdom The Director, Marine Biological Laboratory, Plymouth (Oct. 23). A scientific office? under the Air Ministry, primarily for duty at the Royal Aircraft Establishment for design and research work in connexion with high speed supercharged internal combustion engines and with special reference to research on blowers—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants, quoting A 220 (Oct. 24) A research assistant for blast furnace reactions research at the Imperial College of Science and Technology -- The National Federation of Iron and Steel Manufacturers, Caxton House (East), Tothill Street, S.W.1 (Oct. 25) demonstrator in morganic chemistry in the University of Leeds - The Registrar, The University, Leeds (Oct. 26). An Inspector under the Alkalı, etc., Works Regulation Act, 1906 The Director of Establishments, Ministry of Health, Whitehall, S.W I (Oct. 29). An assistant lecturer in economics and political science in the University College of South Wales and Monmouthshire--The Registrar, University College, Cardiff (Oct. 29). A lecturer in hygiene in the department of education of the University of Bristol -The Registrar, The University, Bristol (Nov. 12). An assistant research physicist at the Gramophone Company, Ltd.—The Gramophone Company, Ltd., Hayes, Middlesex (quoting Z14).

DETECTION OF SCHAUMASSE'S COMET. This periodic comet, which was discovered by M. Schaumasse at Nice in 1911, and seen again on its return in 1919, has now been detected by Prof. G. van Biesbroeck at the Yerkes Observatory on Oct. 4d 10h 22·8m U.T., in R.A. 11h 6m 2·5s, N. Deel. 12° 57′ 59″, magnitude 12. The position is in excellent accord with that derived from the elements given by Dr. G. Merton in Mon. Not. Roy. Ast. Soc. for May last, the time of perihelion passage being Oct. 1.43 as compared with the predicted value Oct. 1.54. The comet is very badly placed, being low in the east at dawn, but it will be even worse placed at its next return in 1935, so it is fortunate that it has been found, as if missed for several returns it would have been difficult to find it again. This is the second comet this year for which Dr. Merton has predicted the perihelion passage within a tenth of a day; the other was comet Grigg-Skjellerup. In the present case, the forecast by the Nice astronomers was Nov. 19, seven weeks too late, so that the comet would not have been found if this had not been corrected.

THE TOTAL SOLAR ECLIPSE OF JUNE 29.—Forschungen und Fortschritte for Sept. 20 contains an article by Dr. H. Kienle, of the Observatory of the University of Gottingen, describing the expedition from that observatory to Gallivare, Swedish Lapland, to observe the eclipse. The height of the sun was 27° and the duration of totality 42 seconds, these being practically the greatest values obtainable at any land station; in consequence it was selected by ten different expeditions from Germany, Holland, Sweden, Esthoma, Russia.

The programme of the Gottingen party included flash spectra with a slit spectroscope, measures of radiation with a photo-electric cell, and photometry of the corona. The radiation measures began an hour before first contact, and continued until an hour after last contact. The sky was clear except for two bands of clouds that were near the sun during totality. These interfered with the observation of the second flash and with the later corona photographs, but the rest of the programme was carried out successfully. Totality is described as "Eine besonders helle und schöne Erscheinung, die nur leider viel zu kurz andauerte"; but details of heresults are reserved for a future paper.

OBSERVATIONS OF THE VARIABLE STAR Z HERCUIA -Bull. Internat. de l'Acad. Polonaise des Science, contains a series of observations of this star made by M. Jean Gadomski of the Observatory of Cracow at the mountain station on Mt. Lysina (3000 feet The period of light-variation falls short of high). 4 days by only ten minutes; in consequence it is difficult to follow all the phases of the star at a single station. However, by making 141 observations on 38 nights in 1923, the author succeeded in determining the whole of the variable part of the light curve. The eclipses last altogether 9.6 hours, just a tenth of the period: the curve seems to be quite symmetrical about minimum, implying that the orbit is appreciably circular. The light is stationary for 2.2 hours at minimum, which shows that the eclipse is total or annular for that period; the rise and fall are rapid for 2.4 hours before and after minimum, and slow for the rest of the eclipse. The magnitude is 7.19 at maximum, 8.01 at minimum.

The study of variable stars is one of the special lines of work undertaken by Poland; also the computation and publication of ephemerides of many of them. Observations of eclipsing variables, when combined with spectroscopic observations of radial velocities, give valuable information on the diameters and surface brightness of the stars.

Scottish Brochs.—In Antiquity for September, Mr. Alexander O. Curle discusses the origin and structure of the broch—the characteristic defensive structure of the north and west of Scotland, consisting of a circular tower surrounding an open court, built of dry masonry without mortar or other binding material, and of which the height originally in some cases must have been as much as 60 feet. The walls at the base are usually 15 feet thick and contain series of superimposed galleries. A puzzling feature, a ledge projecting about 12 inches from the interior of the wall, is now explained in the light of excavations at Dun Troddan, as the resting place for beams extending to posts circling the interior and forming the roof of a closed coloniade around a central hearth open to the sky. The brochs have no relation to the Nurhagi of Sardinia, which differ from them ossentially in structure and purpose. Their closest analogies are to be found in the galleried duns or promontory forts and the so-called 'semi-brochs' of the west of Scotland. The distribution of the broch points to its origin in the north and west of Scotland, those found outside this area being due to an extension of tribal influence from the north. In date they are to be regarded as not earlier than the Iron Age, while the occurrence of Samian ware. Roman coins, and other objects, indicates that they were occupied at the time of the Roman invasion and in the second century A.D., though probably they date back some hundreds of years before that time. They probably were occupied for some time later, but from the absence of wheel-made pottery and Viking relies, it cannot be asserted that they survived to the eighth

The Birds of Ancient Egypt.—In the Nineteenth Century for October, Prof. R. E. Moreau publishes a study of the birds depicted on the monuments of ancient Egypt. Bird forms appear with great frequency in reliefs and paintings on tomb walls. Yet a closer examination of this great mass of material reveals that there is much repetition and continuous copying. The earliest work is the best. Three flerent kinds of geese at Medum were painted with the cat faithfulness. Nothing equals them in later Egyptian history or in the western world until fifty

years ago. The uncoloured reliefs of Sakkara of the fifth dynasty come next to the paintings at Medum. The earliest bird relic is an exquisite ivory figure of a nightjar of predynastic age, before 3400 B.C. at the latest This bird does not appear in Egyptian art again. In the marsh scenes of the Tomb of Ti a large number of birds are shown, ibises, gallinules, herons, spoonbills, cormorants, and spur-wing plovers. Genet cats crawl through the papyrus raiding the nests. An exquisite scene of a kingfisher fluttering round a cat's head while its mate hurtles down in defence of the half-fledged young was copied repeatedly in all its details in later times. In the paintings a number of traps are set for the ornithologists in the restrictions imposed upon the colourist by his palette. Thus gray is represented by a strong bluish green. Mummied birds make only a late appearance in the twentieth dynasty. Nearly thirty species of raptorial birds have been identified at Kom Ombo. Apparently the practice was intended in honour of the hawk-headed god Thoth. Mummied ibsses come from Sakkara. They honour Isis and apparently are connected with the idea of fruitfulness. Some birds identifiable have now disappeared from Egypt—the red-breasted goose, the chanting goshawk, and the sacred ibis. In numbers there must be great impoverishment.

Captive Crickets—Under the title of "Insect Musicians and Cricket Champions of China," Mi. Berthold Laufer, of the Field Museum of Natural History, Chicago, has recently issued an interesting brochure on the ancient Chinese custom of keeping crickets in captivity. It appears that in A.D. 618–906 they began to keep them in cages in order to enjoy their song, while in A.D. 960–1298 they developed the sport of cricket fights. The cult of cricket-keeping, and the vessels and instruments employed, are admirably discussed and figured in this pamphlet, which should be read by any one interested in the subject

POPULATION DENSITY AND DURATION OF LIFE IN Drosophila —The influence of the density of population on the duration of life of Drosophila melanogaster has been investigated experimentally and the results analysed statistically by Prof. Raymond Pearl and his collaborators (R. Pearl, J. R. Milner, and Sylvia L. Parker, American Naturalist, 61, p. 289; 1927). The general method of experiment was to introduce the young flies in varying numbers—from 2 to 200 into one-ounce bottles containing 8 c c. of a bananaagar, or other standard food inixture. The total number of flies was 13,000, distributed in 530 bottles, and equal numbers of males and females. The longest duration of life was found to be when the flies numbered 35-55 per bottle, and with larger numbers the mean duration of life declines steadily with advancing density. A wholly unexpected result was that minimal population densities are not optimal for duration of life. The deleterious effect of crowding is most pronounced during the first few days of life, and is exerted even upon those flies that do not immediately die as a result of it.

SILK PRODUCTION IN THE SILKWORM.-In the Journal of the College of Agriculture of the Imperial University, Tokyo (vol. 9, 1927, pp. 119-138), Mr. Jiro Machida discusses the secretion of the silk-forming substance in the silkworm. It is well known that two chief silk substances are produced, fibroin and sericin, but opinions differ with regard to their origin. By some it is maintained that the fibroin is first secreted and a part of it becomes oxidised later into sericin. By others the two substances are considered to be distinct from the beginning. Mr. Machida's methods of study were primarily histological and, after suitable fixation, the silk glands were dissected from the body of the caterpillar and cut into sections. By means of a mixture of equal volumes of 1 per cent. aqueous solution of acid fuchsin, 2 per cent aqueous solution of methyl green, and an aqueous saturated solution of pieric acid, good staming was obtained, the fibroin appearing blue and the sericin purple. From an examination of material treated in this manner, he concludes that fibroin and seriem are secreted as different substances in different parts of the glands, sericin being produced along the whole length of the middle division and the fibroin at the posterior division of each gland.

MITOCHONDRIA AND CELL INJURY.—The September issue of the Journal of the Royal Microscopical Society contains a pictographic review by G. M. Findlay of the changes which occur in mitochondria as the result of injury to the cell—Whether these changes are due to direct action on the mitochondria or to changes produced in the cytoplasm is unknown. The most common qualitative change is in shape—a transformation of rods into granules which occurs in many pathological conditions. It is noted that though qualitative changes can readily be produced by patho-

logical conditions in gland-cells, there is no evidence of corresponding change in the cells of the central nervous system in such conditions as fatigue, poliomyelitis, and botulism. The quantitative variations which occur under different physiological conditions make extremely difficult any estimate of quantitative change under pathological conditions Changes of position of mitochondria within the cell are by no means rare; eq. in tissue culture individual mitochondria pass from the nuclear region to the periphery of the cell and back again, but the reasons for these movements are unknown. Observations on mitochondria in pathological conditions throw little or no light on their function. As first suggested by Regaud (1909), the surfaces of the mitochondria may be the loci of synthesis in the cell Joyet-Lavergne (1927) has found that mitochondria are coloured by sodium nitroprusside, and it is therefore possible that they represent the cell areas in which the auto-oxidisable substance glutathione is concentrated. The review is illustrated by 24 plates, and a list of references is appended.

Crustacea of the North Sea and Baltic.—Recent additions to the ('rustacea in "Die Therwelt der Nord- und Ostsee" (Leipzig . Akademische Verlagsgesellschaft, 1927, Lieferung 8) are the non-parasitic copepods (Copepoda non parasitica, by O. Pesta, Teil X. e 1), the Crippedes (Cirripedia, by P. Krüger, Teil X. d), and the Leptostracea, by Johannes Thiele, in Lieferung 7 (Teil X. g 1). With such a large group as the free-living copepods, much space must necessarily be occupied by the systematic survey, which is here particularly useful, giving keys to the genera of the three groups—Calanoidea, Cyclopoida, and Harpacticoida. The harpacticids being so much less known than the other two, the notes on these are specially welcome. In the biological part the author gives a summary of his own previous work on the relations between the build of the copepod and the method of movement in marme forms, in which he designates three types: floaters, swimmers, and creepers, calanoids being typical of the first, harpacticids of the last, and amongst the swimmers are members of all the groups.

PRODUCTION OF PLANKTON.—Observations were made by Prof. H. H. Gran on the spring production of diatoms in Norwegian coastal waters off Bergen in 1922 (Report on Norwegian Marine and Fishery Investigations, vol. 3, No. 8, 1927). The outburst was of its usual short duration, reaching a maximum on Mar. 23, after which date there was a rapid decrease. The predominant species were Thalassiosira Nordenskioldii and Skeletonema costatum, which each attained a density of more than 200,000 cells per litre. It is suggested that this plankton and the requisite supply of nutrient salts came in the Baltic stream which issues from the Skager Rack, where a similar plankton occurs about a month earlier. Working on Mohn's figures for the average velocity of the Baltic stream, 0.4 sea mile per hour, it would take just a month for water from the Skager Rack coast of Sweden to reach Bergen. Collections taken in the Hardanger Fjord showed a different diatom population, with Leptocylindrus minimus the most abundant form (up to 2½ millions per litre). On the basis of the increase of oxygen, shown in the coastal waters to run parallel with the diatom maximum, the production down to a depth of 10 metres was estimated as being 1.4 gm. glucose per cubic metre for the minimum value for three weeks. It must be realised that during this period much oxygen was probably being lost to the atmosphere from the supersaturated surface waters, and results from culture experiments gave consider-

ably higher values. By this means the productives estimated as 5.2 gm, glucose per cubic metro 20 days, or an average of 0.26 gm, glucose per 24 houper cubic metro.

INDIAN FOREST PLANTS. - In a recent number of the Indian Forest Records (vol. 13, pt. i., 1927) Mr. R. N. Parker, Forest Botanist at the Research Institute at Dehra Dun, commences a series of "Illustrations of Indian Forest Plants." The author gives as his reason for undertaking this work that much useful information not generally known is available in the form of specimens accumulated in the Dehra Dun Herbarum, which, it may be mentioned, contains specimens collected by Wallich and Roxburgh. He quotes Sir D. Prain ("Bengal Plants," p. 263) as writing, "It is not a matter for congratulation that we know less about trees so important as the Garjans than was known by English residents in Bengal 90 years ago." Mr Parker says he hopes to show that this is no longer true, and opens his series with an account of the Dipterocarps of Gaertner and Roxburgh. A further example is given of the necessity and usefulness of the present work. In the "Flora of British Indu" two species of Anisoptera are mentioned, namely, A. oblonga Dyer, described in 1874, and A. glabra Kurz, described in 1873. In the "Flore générale de l'Indo-Chine," published in 1910, these two Indian species are mentioned as "espèces incomplètement connues." The Anisopteras, like the Dipterocarps, are forest trees of the largest size, and it is highly desirable that they should not remain obscure; as if they extend into neighbouring regions such as Siam, Indo-China, and Malaya they will mevitably be renamed, if this has not already been done, thus causing a useless multiplication of names. Much of the material which Mr. Parker has had to work on, especially that from Burna, has been collected from marked and numbered trees which have been visited periodically by the forest staff in order to collect leaves, twigs, flowers, and fruits when available on the tree. The successful collection of specimens from big trees is not an easy matter when we picture the dimensions of one instanced 110 feet high, 7 feet girth, and 62 feet to the first branch! In the Part I. of Mr. Parker's series here dealt with he describes five species of Dipterocarpus (costata Gaertn., turbinatus Gaertn, pilosus Roxb., tuber. culatus Roxb., and alatus Roxb.). The series will be of undoubted value to the botanist, but it will be equally welcomed by the forest officer; for those who have worked in the Chittagong, Arrakan, Burma, and Andamans forests are well aware of the confusion which has reigned in the correct identification of these species of a fine genus of timber trees.

The Genera of Magnolies. In the Kew Bulletin (No. 7, 1927), J. E. Dandy gives the results of a much-needed critical study of the Magnoliese, in so far as it concerns the tribe Magnolies. For a long time much of the confusion which has existed in the group has been due to the various interpretations of the limits of the genera. The author has now been able to assemble at Kew for the first time the type specimens of nearly all the species of the tribe. By relegating the very distinct genus Liriodendron to a tribe of its own, he finds that the remainder of the family, the true Magnoliese, form an extremely natural group, about the number of constituent genera of which there has never been any uniformity of opinion. Ballon arranged the genera under five sections of the one genus Magnolia. The present study suggests that taxonomically Baillon's unigeneric view is untenable, and nine genera, four of them new, are recognised, namely, Talauma, Manglietia, Magnolia, Aleimus

omadendron, Pachylarnax, Elmerrilla, Micholia, il Kmeria. Ot the new genera, Aleimandra is a str-off from Michelia, on account of the terminal instead of axillary flowers; Pachylarnax is based on a species hitherto undescribed, and unique in the family on account of its capsular fruit, Elmerrillia resembles some species of Michelia in general appearance and in the axillary flowers, but differs in the sessile gynecium and introrsely dehiscent anthers, Kmeria (formerly Magnolia Diaperreana) has unisexual flowers and a mode of dehiscence quite unknown in the rest of the family.

Variation of Radioactivity of Hot-springs.—In the Science Reports of the Tohoku Imperial University, vol. 16, No. 5, K. Shiratori gives detailed results of the investigation of the radioactivity of hot-springs in the west of Honsyu, carried out in the summer of 1925, and compares his figures with those obtained by Ishizu, made in 1913–14. In the interval, the radioactivity of six springs has increased, whilst that of four springs has decreased. An earth-quake intervened in the interval.

Soundproof Houses.—Two recent papers of the Bureau of Standards (Scientific Paper 552 and Technologic Paper 337), by Mr. V. L Chrisler, deal with the building construction problem of preventing sound from passing from one room to another in a tenement house. Each wall of a room acts as a diaphragm fixed at its edges, but capable of being moved backwards and forwards at its centre by sound waves which impinge on it. The stiffer and heavier it is the less its motion and the less the sound it transmits to the room on the other side. With a compound wall having an air space, the intervening air acts as an ineffective connexion between the two surfaces, so that little sound is propagated through the wall. If, however, the two surfaces are connected by studs, struts, or cross ties, the transmission is greatly increased, and this is found to be true to some extent of many of the fillers which are at present introduced into the air space as sound insulators. It is recommended that the two surfaces of the wall should not be tied together in any way, and that the weight of each should be carried by felt pads.

CONDUCTION THROUGH METALS.—In a communication from the Physikalisch-Technischen Reichsanstalt, published in the Zeitschrift fur Physik (vol. 44, p. 615), E. Gruneisen and E. Goens have described some attempts to systematise the data on thermal conduction through metals of simple crystalline form, making use very largely of new values obtained by them for the conductivities between  $0^{\circ}$  C. and  $-252^{\circ}$  C. They have found that there is a linear relation between the reciprocal isothermal conductivities for heat and for electricity with different specimens of a substance, and suggest that the thermal conductivity is partly 'metallic' and partly non-metallic.' The former component satisfies the Wiedemann-Franz relation, and gives a value for Drude's constant which is close to that predicted from the theory of electrons, whilst the second component depends only on the temperature. The total resistance can be expressed in terms of the characteristic functions introduced into the theory of specific heats by Prof Debye. Although many of their measurements were made both with single crystals and with ordinary test-pieces, it is still uncertain if the size of the individual grains in the latter is of any consequence.

THE ANNEALING OF COLD - ROLLED STEEL.—
Edwards and Kuwada have studied the annealing of hom ad steel subjected to varying degrees of reduction

No. 3024, Vol. 120]

by cold-rolling. Their results are stated in a paper read at the Glasgow meeting of the Iron and Steel Institute. The temperature at which the hardness begins to be removed falls as the degree of cold work is increased and the rapidity of the removal increases at the same time. Around 500° C, just before softening sets in, there is a distinct tendency for the hardness to rise somewhat. The most effective range of temperature for softening the steel lies between 550° and 650° C. The curious fact was observed that on annealing at 650°-750° C, specimens which had been subjected to an intermediate amount of cold work, 11 6-19 5 per cent, reduction, become softer than either the original material or that which has been either more or less severely deformed.

SILICA GEL AS A MEDIUM FOR DRYING BLAST.-Whether dry blast in iron smelting is, or is not, economically useful may perhaps be still a matter of opinion. A paper dealing with the application of silica gel for this purpose, read at the Glasgow meeting of the Iron and Steel Institute, however, appears to carry the subject a good deal further from the purely technical point of view. The main features of the use of the material from the blast-furnace point of view are that at room temperatures it can adsorb up to at least 20 per cent. of its weight of water with almost perfect efficiency, and that by raising the temperature to about 600° F., this water can be driven off, leaving the re-activated gel ready for another cycle. It is not advisable to reduce the water content below about 5 per cent and about 2 lb. of gel per cub. ft. of air to be treated a minute is required. A plant to deal with 35,000 cub ft. of air a minute has been erected and run satisfactorily for the past year. It consists of six units, of which five are in operation, while the sixth is being re-activated, the normal period for this being about 14 hours reducing the moisture in the blast to about 12 grains per cub ft., the output of the furnace has been considerably increased, with a distinct saving of fuel. The labour required is almost negligible, the power needed about 20 h.p., while the life of the gel appears to be long. Blast-furnace gas is used to supply the heat for the treatment of the gel, which, like the air needed for the combustion, is filtered before use. The dehydration of the blast can be carried much below the present figure if it be desired, and the figure of 0 1 grain of moisture a cub. ft. is mentioned.

THE CONSTITUTION OF GENTISIN.—The constitution of gentism, first isolated from gentian root in 1821, has been definitely settled by the synthesis of the only possible alternative substance, which was found to have different properties from gentism. Gentism is the monomethyl ether of gentisein, which in turn is 1:3:7-trihydroxyxanthone. The work, by Shinoda, is described in the August number of the Journal of the Chemical Society.

Synthesis of Taurine. -Taurine, 2-amino-ethyl-sulphonic acid, occurs in the tissues of various lower animals and in secretions of higher animals, where it is probably formed from the amino-acid, cystine. It has been synthesised by several methods, first by Kolbe in 1862, but these are unsatisfactory. Marvel, Bailey, and Sparberg, in the July number of the Journal of the American Chemical Society, show that a modification of a method proposed by Köhler in 1898 gives fairly satisfactory yields. It consists in treating 2-bromo-ethylsulphonic acid or its sodium salt with aqueous ammonia to give a mixture of taurine and sodium bromide, from which pure taurine is easily obtained by crystallisation from alcohol. Full experimental details are given in the paper.

# Leipzig Meeting of the International Commission for the Exploration of the Upper Air.

URING the week Aug 28-Sept. 3, the ancient city of Leipzig was the scene of an exceptionally well-attended meeting of the International Com-mission for the Exploration of the Upper Air. Of the European countries, members of the Commission were present from Norway, Sweden, Denmark, Russia, Poland, Hungary, Austria, Germany, Holland, Great Britam, France, Spain, Italy, and Greece. Extra-European countries were represented by Dr. H. H. Kimball, of the Weather Bureau of the United States of America, and by Dr. Ooishi, the Director of the Aerological Observatory of Tateno, Japan. Sir Calbert Walker, though no longer holding an official position, may perhaps be regarded as having established contact with India Letters expressing regret for unavoidable absence were read at the opening meeting from various other members from over-seas

The main business before the meeting was the consideration of a specimen volume containing the observations in the free atmosphere made on the international days of the year 1923 which the bureau of the Commission had been charged to prepare The question of reviving the arrangements for publishing in collective form the data referring to the international days has been before meteorologists ever since the termination of the War, which had brought the old arrangement to an abrupt conclusion. It was discussed in detail at a meeting of the Commission held in Bergen in 1921, but it was found impossible to evolve a practical scheme or even to formulate the basis on which international contributions to the cost should be asked for. The matter dragged on until 1924, when it came before the Meteorological Section of the International Union of Geodesy and Geophysics. That body came forward with the suggestion that the preparation of a specimen volume containing one year's observations would afford the best means of furthering the enterprise on the principle e'est le premier pas qui coûte, and allocated from the funds at its disposal a sum of £500 for the purpose. That sum was afterwards increased by contributions from other sources and it became possible to take the work in hand. The general lines which the publication should follow were agreed upon at a meeting of the Commission held in London in April 1925, and the task of preparing it was entrusted to the president, Sir Napier Shaw, and secretaries.

The volume submitted at Leipzig represents the result of their labours. It is in tour parts. Part 1 (p. 28), the introduction, sets out the Règlement approved by the Commission in London for the guidance of the editors. It enjoins the use of systematic units and the specification of geopotentials in place of the more usual geometric heights. This has rendered necessary conversion tables and some further explanation of the methods of applying the règlement adopted by the editor. The Introduction ends with a list of stations co-operating in the international investigation of the upper air during 1923 and 1924, with their co-ordinates and geopotentials, and also the local time corresponding with G.M.T.

Part 2 (p. 40) consists of an index of the data available for each international day, and a collection of synoptic charts showing for each of the days the distribution of pressure over the whole world. This is probably the first occasion on which charts have been published showing the distribution over both hemispheres. The information has in general been compiled from the daily weather reports of the

For the northern hemisphere, various countries thanks to the daily maps of the Pacific Ocean published in Japan, and the corresponding information available in the Meteorological Office for the Atlantic, representation by means of isobars has been possible over the greater part of the area. For the southern hemisphere, much of the information has been supplied specially Representation by isobars is confined to the land areas; for the oceans it has only been possible to give individual readings representative of observations on islands or ships. The inclusion of world maps in a volume devoted to observations of the upper an is eloquent testimony that the study of the upper air has become truly international and world-wide in its scope. The maps form a standing challenge, on one hand to meteorologists in the regions remote from the areas directly controlled by the larger meteorological services to contribute their share to the common stock, and, on the other hand, to those working in the meteorologically more favoured regions to think in terms of world meteoro-

Part 3 (p. 148) sets out the data in tabular form. The British reader will note with satisfaction that m addition to the observations from British and Canadian stations, the Empire is represented by pilot balloon observations from Australia, Ceylon, South Africa, Samoa, and Hong Kong The labour of presenting the very heterogeneous material submitted by the individual co-operators in the homogeneous form enjoined by the Commission's règlement has been very great, but the task once achieved, the volume forms an invitation to all to adopt the standard form in the primary tabulation of their meteorograms, whereby the task devolving on future editors would be much reduced. It is indeed a case of the first step being the most expensive, but it must of course be borne in mind that, as the years go by, the number of co-operators and the amount of material they will supply is bound to increase.

Part 4 (p. 20) consists of a collection of tephigrams, or entropy - temperature diagrams for the ascents of registropy; bulkeyer

of registering balloons.

Such was the specimen volume 1 submitted to the Commission. Its printing has been entrusted to the Cambridge University Press, which fact may be taken as a guarantee that the selection of types and printing leaves nothing to be desired. A considerable part of the time of the meeting was taken up in exploring the possibilities of making provision for the publication of similar volumes for future years. Such volumes might be regarded as complementary to the annual volumes of the Réseau Mondial published by the Meteorological Office, which gives a monthly résumé of surface conditions for the whole world. Ultimately it was decided that an appeal, signed by the past and present presidents of the Commission, Sir Napier Shaw, Prot. V. Bjerknes, and Dr. Hergesell, and by the president of the International Meteorological Committee, Dr. E. van Everdingen, should be circulated to all Meteorological Offices asking for annual contributions to the cost of the publication.

Considerable discussion arose on the question of the use of geopotential in preference to the more usual geometric height as the vertical co-ordinate. From the point of view of organisation, the question is one of considerable importance, for on it depends whether

Copies may be obtained from the Secretary of the International Commission for the Exploration of the Upper Air, c/o The Royal Meteorological Society, 49 Cromwell Road, S.W.7. Price, £2.

Tervers, when tabulating the traces of their cteorographs, should evaluate the pressures, tem-fratures, etc., corresponding with specified geopotentials, or whether they should be asked to give corresponding values for specified heights. It is scarcely practical politics to call on them to undertake the labour of tabulating in both forms or to print both sets of results in extenso. The reglement approved in London in 1925 specified the meteorological values corresponding to the geopotentials 1000, 2000, 3000 . . dynamic metres, but the editors of the specimen volume found themselves unable to comply with that instruction, as the data for 1923 had been submitted by the co-operators before the date of the London meeting and had been computed for steps of 1000 (geometric) metres The corresponding evaluation for steps of 1000 dynamic metres can only be satisfactorily performed by reference to the original records, and the editors had perforce to give the data "aux hauteurs kilométriques définitives au lieu des niveaux géodynamiques". The Leipzig meeting reassimmed the decision taken in London two years earlier, and it thus remains an instruction to the editors of future volumes to publish the values for specified geopotentials as soon as the material shall be available in that form, and an invitation to cooperating observers to reduce their observations in that manner At the same time, there was a strong feeling that geometric height should not be entirely eliminated from the publication, and a small subcommission was appointed to consider what modifications of detail could be made in the tables in order to give heights as well as geopotentials

Among other matters of organisation which came before the Commission was the selection of the days for combined international ascents for future years In this matter the Commission followed the programme drawn up at Bergen m 1921, but, in deference to a suggestion by Prof. Exner that the international ascents should be used so far as possible for the investigation of specified meteorological conditions, it was agreed that the president and the regional vice-presidents should not be expected to restrict to the 'international month' their choice of days on which special ascents are made in response to notice circulated by telegram or broadcast. October was specified as the international month for 1927 and March that for 1928.

Attention was also devoted to organising the arrangements for preparing and publishing the observations of pilot balloons for the twelve months commencing July 1, 1917, from the very close network of observing stations that existed during the War. This proposal had been remitted to the Commission by the International Meteorological Committee at its meeting in Vienna in 1926.

Though the greater part of the time of the meeting was taken up with the discussion of questions of organisation, time was found at the afternoon meetings to bring forward a number of purely scientific questions and to receive reports of progress m various branches of upper air work. Summaries of these will be published in due course as appendices to the official report of the meeting.

At the penultimate meeting, the Commission was called upon to make choice of a new president, as Sir Napier Shaw had intimated his firm intention of vacating the arduous post which he has filled with such distinction for so many years. Upon the motion of M Wehrlé, of the Office Nationale de France, Dr. Hergesell, the Director of the Lindenberg Observatory, was unanimously elected president. In proposing Dr. Heigesell, M. Wehrlé referred in a tew well-chosen words to the eminent services which he had rendered to the study of the upper atmosphere during his tenure of the office of president during the years prior to the War. Sir Napier Shaw was mvited to accept the position of honorary president Dr C. W. B. Normand, Director-General of Indian Observatories, was elected vice-president of Region D (India and Philippines) in succession to Mr. J. H. Field. Dr Marvin remains vice-president of Region A (North America), and Dr. Th. Hesselberg (Oslo) and Mr. R. G. K. Lempfert will continue to act as secretaries of the Commission.

This account of the meeting would be incomplete without some reference to the cordial welcome extended to the Commission by the Saxon Government, the University and the Municipality of Leipzig, and by the authorness of the Leipziger Messe. The Minister for Volkswirtschaft, the Rektor of the University, and the Mayor of Leipzig attended the opening meeting to welcome the members of the Commission, at which Dr. Hergesell also spoke a few words of welcome on behalf of the authorities of the Reach. The Minister afterwards took the chair at an official dinner. The authorities of the Messe not only put their organisation for providing lodging ungrudgingly at the service of the Commission, but also invited the members to pay an official visit to the technical section of the Fair. The Municipality entertained the members at a special performance at the Opera Last, but not least, all who attended the meeting will feel that they owe a special debt of gratitude to Prof. L. Weickmann, the Director of the Geophysical Institute of the University, in which building the meetings were held, for the excellent arrangements made for their comfort. Nothing could have exceeded the care with which Dr. Weickmann and his staff had thought out in advance all details which could contribute to the success of the meeting. R. G. K. L.

#### Grouse Disease in Norway.<sup>1</sup>

WE have recently received a memoir by Prof. August Brinkmann on coccidiosis in the willow grouse (Lagopus lagopus) which forms communication No. 16 of the comprehensive investigation on the biology of this bird undertaken by the Bergen Shooting and Fishing Society. The object of this investigation, which is on similar lines to that of the British Grouse Commission, is to inquire into the causes of the fluctuation in the stock of willow grouse.

Prof. Brinkmann found that the development in the willow grouse of *Emeria avium*, the causal organism of cocodosis, agrees in general with the account given by Prof. Fantham of its development in grouse. It differs from the Eimeria arium of hom 'ergens Museums Aarbok, 1926, Naturv. 1ackke, No. 9 (1927).

domestic fowls and turkeys in that the large subepithelial cysts with their numerous merozoites found in these birds are not present in the willow grouse. Oocysts from the willow grouse are on the average larger than those from the fowl, and they are shorter but broader than those from the grouse; their size and shape, though their variations overlap those from other birds, stamp them nevertheless as a particular type, supporting Vervey's view that Eimeria arium is to be found in various birds as phenotypes more or less different in form.

Examination of the willow grouse shows that the jejunum was most generally infected and that the duodenum was also frequently infected. In both these parts of the intestine the whole life-cycle of Emeria takes place; the duodenum does not appear to be, as in the grouse, the special site of schizogony. The cacum may be tull of cocysts, but its epithelium is always free from the intracellular stages.

In the willow grouse cocedosis is especially a disease of young birds—75 per cent of those examined were infected. It is also common in the adult birds, 49 per cent, being found infected, but the infection is much more severe in the young birds. The number

of parasites present in severe cases has been estimated to be several millions.

The course of the infection is similar to that in grouse; if the young bird survives the acute stage, the disease passes into a chronic stage, during which oocysts are produced, though in meagre numbers, for a protracted period. Severely infected birds fly little if at all when they are flushed, nor do they try to bide themselves, but remain sitting in quite open ground.

and can easily be taken with the hand

In a concluding chapter, Prof. Brinkmann points out that investigations in Norway during the last ten to fifteen years show that neither migrations, meteorological conditions, not the toll taken by beasts of prey and by man can be considered as having had any decisive influence on the increase or decrease of the stock, but that the decrease must be due to the epizootics by which the stock has been ravaged from time to time. The only known epizootics of the willow grouse are those due to coccidiosis, for hitherto the presence of Trichostrongylus pergracilis, the nematode worm which causes great mortality among adult grouse, has not been proved. Moreover, the known tacts indicate that it is the disease in the young willow grouse which decinates the stock, and that improvement in the stock is correlated with a decrease in the disease

In the fluctuations in the stock of willow grouse until the 'inneties, the intervals between the good years were of fairly short duration—a few years only—but the last bad period has extended from the year 1912-13 to the year 1925-26, which suggests that

some new factor is exerting an influence. P Brinkmann considers this new factor to be the her toll which has been taken of the Norwegian birds He regards as proved that birds of prey have a tayourable effect on the stock of birds, as they take more of the sick than of the healthy buds. One result of the decimation of birds of prey was an enormous increase in the stock of willow grouse which culminated in 1911. But as no attempt was made to preserve the stock by having gamekeepers to collect sick and dead game and to cleanse infected areas by burning the heather--which would have been impossible under Norwegian conditions-the result was a complete collapse of the stock. This was due to a violent epizootie (coccidiosis) which, because the coveys lay very close together in the summer, had exceptionally tavourable conditions for development. The epizootic has continued year after year, and it was not checked until the stock had become much reduced. The coveys then lay so far apart during the breeding season that the risk of infection was considerably diminished.

Coccidiosis appears to be endemic almost wherever grouse are found, Prof Brinkmann states that he has proved its occurrence in Iceland and Spitsbergen Vervey's view that coccidosis in different kinds of birds is due to a series of phenotypes of the same parasite, Eimeria avium, which can be transferred from one species of bird to another, is in accord with the Norwegian observations that there was coccidiosis simultaneously among willow grouse, ptarmigan, black game, and capercarlzie, and that at the time when the epizootic was at its height the small birds also disappeared in various places. On these grounds, Prof. Brinkmann concludes that it would be impossible to exterminate Eimeria arium. He recommends less destruction of the birds of prey so as to endeavour to return to the conditions before the 'nmeties, when, though there were fluctuations in the stock of willow grouse as great as they are new, the

bad periods were of shorter duration.

#### Sex-change in the Oyster.

A LONG and fully documented paper by Dr. J. H. Orton (Jour Marine Biol. Assoc., 14, 4, May 1927, pp. 967-1045) forms Part I. of an account of the observations and experiments which he has been carrying out for some years past on sex-change in Ostrea edulis; it deals with the change from female to male. The sex-physiology of the oyster well ments elaborate study, and Dr. Orton has been successful in clearing up many debatable points and giving a coherent account of the curious phenomena myolved.

The material examined by Dr. Orton has been extensive; more than 1000 female-functioning systers at about the time of spawning and at intervals thereafter have been closely examined for the purposes of this part of the work. While a number of undoubted hermaphrodites exist, and some curious inter-sexual types, Dr. Orton confirms the view of Hock and Mobius that the syster is bisexual. But alternation of sex is the rule. The data clearly show that, except for a small percentage of abnormal individuals, all female systers normally change their sex immediately after spawning and develop ripe sperm before their larvæ are set free in the water. Functional maleness continues as a rule for one or two months, when the gonad becomes quiescent; after this period a proportion revert to the female condition and produce eggs. There is reason to suppose that a regular, probably annual, alternation of sex occurs normally.

As to the cause of this swift change over from

female to male, Dr. Orton suggests that it is due to a metabolic rhythm characteristic of the species, whereby the type of metabolism perhaps prodominantly a protein metabolism associated with femaleness changes over to the type associated with maleness—perhaps a carbohydrate metabolism. The hypothesis is advanced that the accumulation of unusable products of the one kind of metabolism is the stimulus for the change over to the other.

Dr. Orton's observations on sex-change in the oyster have led him to discuss in a short but suggestive paper (loc. cit., pp. 1047-55) the fundamentals of a theory of sex-determnation. The sex-chromosome theory clearly breaks down in cases of regular alternation of sex, and Orton proposes in its stead a metabolic theory of sex. He suggests that the X- and Y-chromosomes when present have the function of superimposing upon the general metabolism of the species a metabolism of a particular type to which the gonad responds by producing eggs or sperm. But the same sex-modification of metabolism may be brought about by other means than the sex-chromosomes, as by some fundamental change in the rhythm of metabolism related to the conditions of life

The attempt at a physiological interpretation of sex and of the action of the sex-chromosomes is of course not new, but there is little doubt that such attempts are in the right direction. Dr. Orton's contribution, both of fact and of interpretation, to this difficult.

problem merits close attention.

## Competition and Economic Equilibrium.

DROF. J. SCHUMPETER, a distinguished German economist of the University of Bonn, contributed an interesting paper on "The Instability of our Economic System" to the proceedings of Section F (Economic Science and Statistics) of the British Association at the recent meeting in Leeds pounding the question "In what sense can the present economic system of capitalist production and distribution be said to contain possible causes of instability?" Prof Schumpeter said that by the phrase 'capitalistic system' he understood an economic order characterised by (1) Private property and private initiative; (2) division of labour or production for the market; and (3) credit creation by banks, which latter he considered an essential element of that system Neglecting disturbances which might arise from without the economic sphere and would react on economic life, for example, reactions of a policy of deflation in certain circumstances, he showed that the capitalistic system is in itself economically stable, and would not show any tendency to outgrow the elements of which it consists, and would therefore last indefinitely if left to itself.

Prof. Schumpeter pointed out that, as has been demonstrated by the economic analysis of which the late Dr. Marshall is the greatest exponent, there is to be found under competitive conditions a stable equilibrium of the economic process, to which in given circumstances real life tends to conform. This theorem, it has to be admitted, is not accepted by the 'man in the street,' who, on the contrary, is in the habit of attributing all sorts of instability to competition, though this he usually does under mis-But though competitive conditions apprehension prevailed during the nineteenth century with sufficient approximation to theoretical hypotheses, Prof. Schumpeter pointed out that they certainly do not prevail at the present time, and it is therefore necessary to prove a similar proposition in the case where monopoly is the rule among various industries. This is not so easy a task, and there are many economic authorities who do not admit that a stable equilibrium of economic life can exist in this case. Nevertheless, such equilibrium can be shown to exist. It can also be proved that the increase of population is never by itself a cause of economic instability.

Prof. Schumpeter next went on to explain that there remains the fact that the business cycle destroys the state of equilibrium, which may have established itself. The business cycle cannot be accounted for by outside impulses such as harvests, wars, and so on, but is, on the contrary, the necessary form which economic evolution takes under capitalistic conditions. But although every boom destroys an equilibrium, every depression tends to establish a new one, and there is nothing in these recurring waves of prosperity and depression to affect the capitalistic system as such, nor are extensions and contractions of banking credit causes of instability.

Economic stability, however, Prof. Schumpeter stated, does not imply or guarantee political or social stability, and a position of stable economic equilibrium may be socially or politically unstable. For a variety of reasons the political and social circumstances of our time are in fact unstable in the highest degree. By its own working the capitalistic system evolves a mentality and a way of arranging life and looking at life which is bound to undermine what are regarded as indispensable psychological bases of capitalistic sociaty.

Our modern attitude towards taxation, inheritance, home life, etc., which attitude is not dependent on

economic necessities, are illustrations of the development of this psychological process. The capitalistic system provokes discussion, and discussion is the beginning of all revolutions. When psychological reactions have proceeded far enough they may exert a destructive effect on the system itself by removing the motives which have been the mainsprings of that system. People may get into a mental attitude in which they would do away with the economic system without any economic pressure and even against economic interests. If the capitalist system passed away in that fashion many other things would necessarily die, including even, as a possibility, family life as we now know it.

#### University and Educational Intelligence.

ST Andrews.—At the autumn graduation ceremony on Friday, Oct 7, the Vice-Chancellor, Sir James Irvine, announced that the donor of the gift of £100,000 to the University was Dr. E S Harkness, of New York, well known on both sides of the Atlantic for his generosity in the cause of education than one-fourth of the gift was allocated by the donor towards the cost of building a new residential hall for men students. The intention is to restore the old collegiate system which was a feature of university life until a century ago. The honorary degree of LL D. was conferred upon Prot. John Burnet, who has just retired from the Chair of Greek in the University; Sir Richard Gregory, Dr. Knud Rasmussen, Copenhagen, the Arctic explorer; and Mr. Benjamin Thomson, Rector of Forfar Academy

Co-operation between universities and industrial and commercial firms is increasingly close and effective in the United States and is being systematically fostered by the American Council on Education. Remarkable progress has been made in developing ways and means of securing for educational institutions suitable kinds of trustworthy occupational mformation. Large industrial organisations have co-operated in the task of formulating detailed specifications of the work required to be done by the various classes of persons employed by them, and these 'job specifications,' as they are called, have been proved to be of great value both to schools and colleges and to the employers. The following description of methods of co-operation between the Yale University Bureau of Appointments and the industrial organisations with which it is in touch is based on an article published in the April number of The Educational Record. The Bureau is in touch through its bulletins with about 1200 firms, and almost daily from early in March until late in May, representatives of one or more firms, frequently one of the chief executives, attend at the Bureau to interview undergraduates in their final year. Even where the interviews do not lead directly to appointments they are useful to the undergraduates, for m most cases the firm's representatives are glad to give general vocational advice and talk freely and helpfully even with candidates who are not so much interested in the particular company represented as in obtaining specific occupational data, which is, in fact, regarded by many as the most valuable advantage of the When applying for interview dates—and scheme. many more apply than can be accommodated—the firms furnish an outline of the positions to be filled, salaries offered, nature of work, etc., which enables the undergraduates to judge which representatives they wish to see.

#### Calendar of Discovery and Invention.

October 16, 1759 -The building of Smeaton's Eddystone lighthouse occupied the summers of 1756–1759, and the light was first exhibited on Oct. 16, 1759. The lighting apparatus consisted of 24

candles held in a bronze frame

October 16, 1843.—The name of Hamilton is now chiefly associated with the memorable invention of the calculus of quaternions, of which Hamilton wrote in 1858 to the Rev. J. W Stubbs: "To-morrow will be the fifteenth birthday of the Quaternions. They started into life full-grown on the 16th October 1843, as I was walking with Lady Hamilton to Dublin, and came up to Brougham Bridge-which my boys have since called Quaternion Bridge. I pulled out a pocket-book which still exists, and made entry, on which at the very moment I felt that it might be worth my while to expend the labour of at least ten or fifteen years to come." In another letter, written some years atterwards, Hamilton said: "Nor could I resist the impulse—unphilosophical as it may have been-to cut with a knife on a stone of Brougham Bridge, as we passed it, the fundamental formula which contains the Solution of the Problem.'

October 17, 1741.—On this day Linnæus, who had himself travelled in Lapland, Denmark, Germany, Holland, France, and England, pronounced before the University of Upsala his "Oratio de Peregrinationum intra Patriam necessitate." He displayed the usefulness of such excursions, by pointing out to the students that vast field of objects which their country held out to their cultivation; whother in geography, physics, mineralogy, botany, zoology, or economics; showing the benefit that must accrue to themselves and their country as rewards of their diligence.

October 18, 1892.—In the development of long distance telephony in America, Theodore Vail played a leading part. He first connected Boston with Salem, then Boston with New York, and on Oct. 18, 1892, New York was connected with Chicago, Graham Bell being the first to speak over the new line.

October 20, 1868.—Sir Norman Lockyer's notable spectroscopic discoveries were made known to the Royal Society in a letter dated Oct. 20, 1868, in which he stated: "I have this morning perfectly succeeded in obtaining and observing part of the spectrum of a solar prominence. As a result I have established the existence of three bright lines in the following positions:—(i) Absolutely coincident with C. (ii) Nearly coincident with F. (iii) near D."

October 20, 1880.—The first public lighting of a

hall in Great Britain by means of the meandescent electric lamp was carried out by Swan on Oct. 20, 1880, in the rooms of the Literary and Philosophical

Society of Newcastle.

October 21, 1824.—The home of the portland cement industry was Leeds, where Joseph Aspdin, a stonemason, discovered that by mixing finely pulverised lime with clay in certain proportions, burning it at a high temperature, and then grinding the product to powder, he obtained a new building material which, with the addition of water, when set, produced a block resembling Portland stone. He took out a patent for his invention of 'Portland cement' on Oct. 21, 1824. A century later a memorial to him was placed in Leeds Town Hall, when it was stated that the annual production of portland cement was 50,000,000 tons.

October 22, 1797.—The use of the parachute as a means of descending from balloons was due to the French aeronaut, Garnerin, who made his first descent with one on Oct. 22, 1797

National Academy of Sciences (Proc., Vol. 13, No. 8, August). -- Carl H. Eigenmann and George S. Myers A new genus of Brazilian characin fishes allied to Bivibranchia E. F. B Fries: Nervous control of xanthophore changes in Fundulus. The killifish changes in colour to correspond with its background by means of the expansion and contraction of melanophores and xanthophores. Control of the latter is mainly through a discriminating pigmentmotor centre in the central nervous system. -Solig Hecht: A quantitative basis for the relation between visual acuity and illumination. Keenig found that visual acuity increases nearly as the logarithm of the intensity of illumination; hence the number of rods and cones in the retina can be varied functionally. This can be accounted for quantitatively by assuming that the sensibilities of the individual rods and cones vary about a mean in a manner similar to that in which a population varies. lowest intensities, vision is by the rods; then the cones begin to function, and since they come into action ten times as fast as the rods, visual acuity becomes a function of the foveal cones and increases to a maximum. Observations on colour-blindness can also be explained.—David White: The flora of the Hermit Shale in the Grand Canyon, Arizona. This shale constitutes the upper 300 ft. of the red beds in the Grand Canyon and is of Lower Permian age. The flora includes European conifers and pteridosperms and many Uralo-Asiatic forms, it indicates a dry chimate possibly not much number that of northern New Mexico at

esent day.—William H Gates: Linkage of short Gr and density in the house mouse. Linkage appears to be complete.—Willard J. Fisher: Note on corrections to H. A. Newton's "1850 dates" of meteor showers -Carl Baius: Reciprocating acoustic vibration on opposite sides of the pinhole, in long quill tubes.—Walter A. MacNair and A. Ellett: Explanation of the incomplete polarisation of mercury resonance radiation.—E. C. Watson: The spacedistribution of the photo-electrons ejected by X-rays Using unpolarised X-rays, the distribution of electrons about the direction of the X-ray beam has a maximum a little forward of perpendicular to the X-ray beam and falls to zero at about 90° on each side of the maximum; it is asymmetrical, particularly with high frequency X-rays Using polarised X-rays, the distribution has a maximum in the direction of the electric vector and does not fall to zero at 90° from this direction; it is symmetrical, but the maximum is less than in the former case. The theory of nuclear scattering explains these effects —Earl E. Libman. Surface tension of molten metals. (1) Copper. The method used is to measure the depression of surface caused by a vertical plate and a vertical tube which are not wetted by the liquid. Copper is inelted in a high vacuum molybdenum wound furnace in a crucible with lid combining a plate and a tube. An X-ray photograph is taken through the entire furnace and the levels of the liquid measured on the photograph. The 'capillary constant' (2 x surface tension/density  $\times g$ ) for copper in contact with its vapour varies from  $0.308 \pm 0.0017$  at  $1083^\circ$  to  $0.297 \pm 0.0017$  at  $1318^\circ$ . The effect of impurities increases with rise of temperature.—A. Keith Brewer. The relation between temperature and work function in thermionic emission. Gas molecules approaching a surface are dissociated into ions by forces regarded as composed of an electrostatic image force, which has the same effect on both ions, and an intrinsic force, which holds one ion more firmly than the other. These forces are opposed by the kinetic energy of agitation. Hence as the temperature rises, the more lightly held ion escapes first. For pure metal surfaces, positive ions escape first; for oxidised surfaces, the negative ions are released first.—F. A. Saunders: On the spectrum of argon in the extreme ultra-violet.-P. R. Heyl: A redetermination of the Newtonian constant of gravitation (see Nature, Oct. 8, p. 529).—Jesse Douglas: Contact transformations of three-space which convert a system of paths into a system of paths.—M. S. Knebelman: Motion and collineations in general space.—G. A. Miller: Felix Klein and the history of modern mathematics.—S. Lefschetz: The residual set of a complex on a manifold and related questions.—Gilbert N. Lewis and Joseph F. Mayer: A disproof of the radiation theory of chemical activation. Pinene was passed at very low pressure through a quartz tube heated by platinum spirals to about 1000° K. At the pressure used there was negligible screening of one molecule by another and a negligible number of collisions because the mean free path was longer than the gas Under these conditions, energy sufficient for about 10 per cent. racemisation is available but no racomisation was detected.—James H. Hibben: Radiation and collision in gaseous chemical reactions. Nitrous oxide and ozone were submitted to infra-red radiation at different pressures; no increase of reaction velocity was observed. The bimolecular decomposition of nitrous oxide at low pressure is entirely heterogeneous. There is no change in the reaction rate of the unimolecular decomposition of nitrogen pentoxide at pressures of 0.2-0.002 mm. hom ala for artificially deformed crana.

#### Science and Philosophy.

THE mild controversies which have been excited by Sir Arthur Keith's moderate and cautious presidential address to the British Association at Leeds suggest that science and scientific method are still regarded with some suspicion by the educated portion of the community. We need not take seriously the objections to the theory of evolution raised on sentimental or religious grounds m so far as these arise from prejudice and belief in authority Science can recognise no authority. and can admit no barrier to the free and fearless use of the intelligence The theory of evolution stands or falls on the "stubborn and irreducible facts" and upon the rational interpretation of them, and we need have no fear of the verdict of any impartial and competent jury, as Sir Arthur Keith has well and truly pointed out.

Another note has, however, been sounded by the wiser critics—a note not so much of antagonism as of doubt whether scientific method has, after all, proved an adequate key to the problems of the universe and of practical life. The Bishop of Ripon has voiced with great frankness this doubt of the adequacy of science. In hinting that the world could get on perfectly well if for ten years every physical and chemical laboratory were closed, he had in mind apparently two things—first, that the progress of science has vastly increased the complexity of man's material environment without improving his moral outlook or adding to his happiness, and second, that not only educated laymen but also specialists themselves are so overwhelme with the rush of new discoveries, new conception that they have no time to envisage the results a whole, to co-ordinate them and see them in the proper relation to other human activities. suggested in reference to the first point tha "patient and resourceful energy" displayed 1. laboratories could be turned to better effect were applied to the human and social proble the day, where clear and resolute thinkin much required. With this contention we propose to deal. Ne sutor supra crepid sound, if unheroic, maxim.

It is rather with the second point t<sup>1</sup> to come to grips, and particularly w gestion—emphasised also by several *Times*—that science is suffering fr philosophy, to its own detriment lessening of its influence on humar character. Dr. Burroughs, in the s to, asked whether amid all our ner

do not sometimes seem to have lost our sense of direction: "How many of our sectional explorers ever ask themselves which way lies the whole? Am I wrong in thinking that the several sciences increasingly feel the need of a philosophy to co-ordinate them?"

Twenty or thirty years ago, this suggestion that science might learn from philosophy would have been received with scorn in scientific circles. There was a spirit of confidence abroad, a conviction that the principles which had served so well and had led to such conquest over Nature were established beyond question, philosophy was branded as metaphysical and dealing in vain abstractions. We find an echo of this great period in Dr. Chalmers Mitchell's provocative and vigorous Huxley Lecture,1 where he roundly asserts that "philosophy, since she was judicially separated from science, although retaining the title 'lover of wisdom,' has made no positive addition to knowledge and has only been a spinner of vain words and barren ideas." This intransigent attitude is, we venture to think, rather unusual at the present day. The last twenty years have seen the foundations of physics torn up and rebuilt, and the change has come about not only by the press of new knowledge, but also to a great degree through keen hard thinking about the fundamental conceptions of the science, through true philosophical criticism, carried out by the physicists and mathematicians themselves. We can no longer rest content with the simple materialistic schema which atisfied Descartes and Laplace. As Prof. A. N. Thitehead writes in his remarkable book, "Science 'd the Modern World ":

The progress of science has now reached a ung point. The stable foundations of physics broken up. . . . The old foundations of tific thought are becoming unintelligible. space, matter, material, ether, electricity, anism, organism, configuration, structure, n, function, all require reinterpretation. is the sense of talking about a mechanical ation when you do not know what you mean hanics?"

r. Mitchell would have us cling tenaciously echanistic method in biology, on the only through its aid has come any ease of knowledge. This is not the liscuss in detail the merits and the fithe mechanistic method in biology; ver, remark à propos of Dr. Mitchell's is polemic against 'vitalism' mostly k, for the alternative to biological un Biology" Huxley Memorial Lecture, 1927. cmillan and Co, Ltd, 1927) 1s. net.

materialism is not necessarily a dualistic vitalism, but some form of organismal or emergent theory, all of which he confounds under the common ban

The mechanistic method, however, is itself an interpretation of Nature. It is, to use Dr. Mitchell own words about vitalism, "a proclamation of a belief and not an inference from observation" Its sole justification is the practical one, that it does up to a point help us to understand the activities of living things. But there are other methods of explanation possible, and it is unwise to rule them out as unscientific Since physics has found a revolution in its fundamental concepts' necessary, it seems dangerous for biology to cluig to the cast-off beliefs of the nineteenth century physicists. It must come to terms, too, with psychology, and give up the hopeless attempt to derive conscious behaviour from tropisms and conditioned reflexes, regarded as purely physical happenings

The time is indeed ripe for a critical revision of need not fear-that this biological concepts. by-ways. It is probable will lead us into mys that there will alwa 3 something left unexloubts the possibility of plained—even Dr. Mitc le—but clear thinking the part interpreting the bservation, but also, not only about the facts own methods of intermore important still, about und render managepretation, will help to rea able the mysteries of organ

· and evolution. Shall we call this criticism onceptions science or philosophy? This brings o the heart of the matter, and to our tentative relusion, which is "orce of science that the nineteenth century r side, and that from philosophy is good for ne co-operation should now be the der of the day. The benefit will be mutual Th. has been some justification for the jibe that losophy deals with words and abstractions, at is apt to be neglectful of the laboriously garn. d harvest of scientific fact. In the recent discer ies both in physical and in biological science, . re is ample material to keep the philosopher bu for years. The man of science for his part can arn much from the philosopher. He can learn 1 bossed and provisional his views of Nature may MON. difficult it is to get rid of irrational presupposit. which may colour all his thought

In his eloquent tribute to Huxley, Dr. Mitche points out that

"He accepted, as a postulate, but admitting it to be a postulate, belief in the rationality of the universe our minds seek to explore. This was the charter of science, conferring a certain right in return for the observance of certain duties. The right was that the writ of science should run whatsoever traditions, beliefs, dogmas, or customs it might destroy. The duties were accurate observation, clear statement, a logical scrutiny of generalisations so that they should not imply and should not seem to imply an iota of necessity, an open mind for new facts, but a cross-examination of the evidence for them the more ruthless in proportion to their apparent contradiction of widely based generalisations—and above all a profession of ignorance in preference to the propounding of acceptance of 'causal' principles which could not be put to the test of experiment."

That is well said, but it does not go far enough Let the clear thinking and the logical scrutiny be applied not merely to the generalisations resulting from observation and experiment but also to the underlying conceptions, the basal philosophies, in accordance with which these generalisations are formed. Let us scrutinise everything—even our most cherished scientific principles.

Coming back now to the broader question of the relation of science to other forms of human activity, we must recognise the limitations of scientific and indeed of any purely intellectual method. There are other aspects of human personality which science does not satisfy, and it would be foolish to extend the dominion of scientific method beyond its proper sphere. We do well to remember that the richness of reality is mexhaustible, both in its manifestation in the external world and in the depths and recesses of personality. Neither science nor philosophy can give more than an abstract and colourless rendering of essential truth, which is approached perhaps most nearly by creative But inside these necessary limitations the exercise of the intellect should be free, fearless, and untrammelled by any dogmatism, prejudice, or dependence on unrealised assumptions

#### Brewing and Malting.

A Standard Manual of Brewing and Malting and Laboratory Companion. Being a thoroughly revised and considerably augmented work, based on "A Handy Book for Brewers," by H. E. Wright, embracing the Conclusions of Modern Research. By John Ross-Mackenzie. Pp. xxiii+415. (London: Crosby Lockwood and Son, 1927) 45s. net.

AS a result of the great change which has taken place in recent times in the nature of the beer favoured by the public, the demands on the skill of the modern brewer are much more exacting than they were on that of his predecessor of a generation

ago. The brilliant and well-conditioned beer of to-day is characterised from the brewer's point of view by a low original-gravity, low alcohol-content, and low hop-rate. These factors, combined with the lack of nutrient matter in the modern wort, place a greater strain on the yeast, and also render the beer more liable to infection. On the other hand, modern scientific methods have provided a weapon with which to combat these difficulties. These are the influences traceable throughout the volume under review, and mark a stage in the passage of brewing from an art to a science.

The book appeared in its original form so far back as 1877, and was intended at that time essentially for the novice. In 1892 it was revised and enlarged under the title "A Handy Book for Brewers," but the author, H. E Wright, died at the time of the publication of the third edition in 1907. In the twenty years that have since elapsed the information has naturally become out-of-date, and the appearance of a revised and augmented work is to be welcomed. The plan and scope of the last edition has been followed fairly closely, though the student rather than the brewer is catered for

The first chapter sketches in outline the complete brewing process, and should prove useful to the beginner if studied in conjunction with the synoptic table at the end of the book, since the brewing operations are dealt with in order in more detail in the subsequent chapters. Brewing-room calculations, chemistry, hydrogen ion concentration and ferments in general provide additional chapters, and the book closes with a brief, elementary description of the brewery and its plant.

In a book which attempts to cover so vast a subject and its ramifications, in which the details of the methods used are largely matters of personal opinion based on experience, it is not difficult to pick out omissions and errors. On controversial points, however, the author has apparently endeavoured to strike a balance between opponents and to produce an argument that is not too bewildering for the beginner. This has involved the omission of a great deal of the most recent investigations on subjects such as starch, yeast, and the preservative powers of hops, though a readable account is given of the earlier work. Again, for example, reference might with advantage have been made to the vexed question of the Mariout barley, which in spite of its favourable analysis, appearance, and powers of resistance to extremes of climate, has been condemned in many quarters. The disposal of brewery by-products is also of sufficient economic importance to justify its inclusion.

The author is at his best when he deals with the varying conditions which influence the practical side of brewing His descriptions of chemical operations, however, are often lacking or out-ofdate. We doubt whether the student will be able to obtain the required degree of accuracy from many of the instructions with which he is provided, especially if his intelligence is assumed to be of such a level that he has to be told which end of the thermometer to insert in the drying-oven! A redeeming feature of the descriptions of the applications of science to brewing is the chapter on hydrogen ion concentration, the theory of which is outlined clearly by F A. Mason. Its usefulness, however, will be largely obviated by the fact that the practical applications of the theory occupy only half a page of this chapter, and nowhere else in the book are they mentioned This is a serious drawback when subjects such as mash-tun treatment, stability of beer, and the optimum conditions for enzymes are under discussion.

It is unfortunate that the book is characterised throughout by an extremely loose form of grammatical expression which at times renders the meaning almost unintelligible. Minor errors and misprints are far too numerous also, and the spelling of many words is rendered correctly in some parts and differently or incorrectly in others. names (Buchner, Marsh-Berzelius, etc.), and the title of Pasteur's classical work on beer, are among the more serious offences in this last respect. There is a lack of references to the original literature, and the frequent mention of a glossary which had to be omitted at the last moment is confusing There is also a paucity of illustrations, the few given being chiefly photographs of plant. The briefest description of the anatomy of the barley-corn, or of the hop, is incomplete without a diagram.

The book is well produced, but the advertisements, which have invaded even the end-papers and the backs of the title and contents pages, are an eyesore.

J. G.

### Plant Diseases.

Manual of Plant Diseases. By Dr. F. Deforest Heald. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Pp. xiii +891. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1927.) 35s. net.

THIS important book is the result of considerable experience in the teaching of plant pathology, which is now a recognised feature of No. 3025, Vol. 120]

agricultural and horticultural training The arrangement and treatment of the subject matter follows that adopted by Dugger in his well-known "Fungous Diseases of Plants," and has been used by the author in his classes during the last ten The book is divided into four sections, the first containing two chapters dealing respectively with the history of pathology and the symptoms of disease, the latter especially should be read by all students of the subject. Section 2 deals with non-parasitic diseases, caused by some unfavourable influence in the plant's environment. The effects of excess and deficiency of available nitrogen and potash in the soil are discussed at length, and examples are drawn from 'sand drown' of tobacco, 'yellow berry' of wheat, and 'potash hunger' of potatoes and tobacco. It is perhaps unfortunate that the important problem of 'leaf seorch' of orchard trees finds no place in the discussion. A considerable amount of useful information is given in other chapters setting out the effects of unfavourable air, light, temperature, and water conditions upon plant growth. 'Bitter pit' and 'scald' of apples are excellent examples of the treatment given to individual disorders.

The phenomenon of photoperiodism, which has attracted much recent attention, is briefly described in three pages. One may perhaps doubt the advisability of including it in such a book, where space is valuable, but if it is worth discussing at all in relation to plant disease, these pages seemquite inadequate for the purpose.

In dealing with diseases proper, the author has selected those which are of economic importance, and has described the history, distribution, symptoms, etiology, host relations, and control of each, together with a list of references at the end of each disease and a brief note of etiologically related diseases at the end of each chapter. The lists of references to literature are extensive, but they are mainly concerned with American investigations. Reference to foreign papers seems desirable.

Section 3 is devoted to virus and related diseases. Only those who have struggled with the mass of literature on this subject can appreciate Dr. Heald's difficulty in compiling a reasoned account of these fascinating diseases. He has succeeded in giving the elementary student an insight into the subject, which should stimulate his interest and appreciation of its importance.

Section 4 occupies two-thirds of the book, and is devoted to parasitic diseases, including those caused by bacterial pathogens, which are classified

in accordance with Migula's scheme. Actinomyces scabies is, however, included among the bacteria Fungus diseases are treated admirably, with good arrangement and up-to-date material. Students should have little difficulty in obtaining a good working knowledge of plant diseases. The section ends with a discussion of diseases caused by parasitic seed plants and nematodes, but the latter chapter does bare credit to the importance of these animal pests. Investigators have the greatest difficulty in distinguishing between parasitic and non-parasitic forms present in diseased material, and many harmless forms have been convicted of evil intent without proper trial. Students should be warned against this.

A good general index is provided, but there is no host index. The volume is well illustrated, and the illustrations are usually effective, but Figs 199-202 are decidedly poor and are not calculated to inspire the student.

The object of teaching plant pathology is to train workers to diagnose and control diseases which are causing serious damage to economic plants the world over. This being so, an effective text-book must include a clear account of the physiology of disease and the principles of disease control. It is regrettable that Dr. Heald has purposely omitted this part of the teaching of pathology from his text-book, which will doubtless be used by many teachers of the subject.

W. F B.

# A New Version of the 'Intellect.'

The Measurement of Intelligence By Edward L. Thorndike, E. O. Bregman, M. V. Cobb, Ella Woodyard, and the Staff of the Division of Psychology of the Institute of Educational Research of Teachers' College, Columbia University. Pp xxvi+616 (New York: Teachers' College, Columbia University, n.d.) n.p.

MANY circumstances invest the present volume with signal importance. Of such an unusual magnitude has been deemed the investigation which it reports, that a special grant was assigned to it by the Carnegie Corporation, and for the last four years Thorndike has so devoted himself to it, as even to give up for its sake his university teaching. Moreover, as indicated above, his entire staff has been collaborating with him.

The account of all this work begins by freely conceding that hitherto mental tests of the intellect have been afflicted with "three fundamental defects": ignorance of what is being tested;

ignorance of how the test-scores should be combined, and ignorance of what the results signify in respect of the intellect

To cope with this situation, the authors in the first place conceive the intellect as having two dimensions: on one hand "altitude", on the other, "width." By the former they mean "the degree of difficulty at which a person can succeed at tasks", by the latter, "the number of tasks that he can succeed with at any specified degree of difficulty."

So far, all is plain sailing enough. But now have to be encountered the "fundamental defects." For these concepts of altitude and width of intellect can serve no useful purpose until we settle what kinds of mental performance the word 'intellect' is really intended to comprise. On this vital point the authors commence in a surprising fashion.

"For a first approximation, let intellect be defined as that quality of mind (or brain, behavior, if one prefers) in respect to which Aristotle, Plato, Thucydides, and the like, differed most from Athenian idiots of their day."

How the mental make-up of these idiots shall ever be ascertained is left unsaid.

Later on, however, a more definite view is advanced and made the actual basis of the present investigation. It is to the effect that every one can take intellect to mean whatever he will.

"What abilities and tasks shall be treated as intellectual is essentially a matter of arbitrary assumption or choice at the outset. . . . After the first choice is made, tasks not included in it, and not even known, may be found to correlate perfectly with the adopted total, and so to be intellectual"

The authors themselves select as their "first choice" what they call "intellect CAVD," composed as follows.

- $\lq\lq$  C. To supply words so as to make a statement true and sensible.
  - "A. To solve arithmetical problems.
  - "V. To understand single words.
- "D. To understand connected discourse, as in oral directions or paragraph reading."

To the study of this "intellect CAVD," then, the whole investigation is really directed, and a very remarkable result is the outcome. Evidence is adduced that these four abilities, C, A, V, and D, jointly constitute one single "total-ability," in the sense of a "unified, coherent, fundamental fact in the world."

With great interest the reader turns to examine upon what sort of evidence such a result has been founded. It consists in the discovery that the different "altitudes" of the intellect CAVD correlate with one another to a degree which—on due correction for attenuation by random disturbances—is little if at all short of perfect unity. This line of evidence in respect of the originally adopted intellect CAVD is just the same, it will be noticed, as that which our previous quotation gives for making any subsequent additions to the purview.

Now comes a curious point which the authors appear to have overlooked. It is that this kind of evidence—perfect correlations after being corrected for attenuation—is precisely that which was introduced by the present reviewer in first demonstrating the existence of what our school calls g. Even the various criteria used afterwards for this purpose (including the latest, that of 'tetrad differences') are merely diversified mathematical forms of expressing exactly the same thing. (For proof of this statement, reference may be made to the reviewer's recent work, "The Abilities of Man.")

It only remains, then, for Thorndike to carry out his programme and ascertain what further abilities correlate perfectly with his initial CAVD, when the correction for attenuation is effected in a suitable manner. Assuredly he will find, just as we have done in the book just referred to, that the range includes all abilities whatever—In this way his "unified, coherent, fundamental fact in the world" turns out to be our g once again, nothing more or less.

Hereby is completed the entire chain by which, link after link, the school of Thorndike has been gradually adopting all the chief doctrines long advocated by ourselves. In such an eventful convergence of originally warring views, we may venture to see a most hopeful augury for the future of psychology as a positive science

# Tycho Brahe.

Tychonis Brahe Dani: Opera Omnia. Edidit I. L. E. Dreyer. Tomus 8. Pp. 471. n.p. Tomus 12. Pp. iv+488. n p. Tomus 13. Pp. iv+398. n.p. (Hauniæ: Libraria Gyldendaliana, 1925–1926.)

THE eighth volume of this monumental edition has the melancholy distinction of being the last that was published in the editor's lifetime. It shows no diminution of the accuracy which always distinguished Dr. Dreyer's work. The editor calls it the third volume of the "Epistolae Astronomicae," a series which is here continued

from June 1597 to June 1601, four months before Tycho's death.

The plan of this volume is the same as that of the second volume of the "Epistolae," the seventh of the whole series, but the subject matter is largely different. While the second volume was mainly occupied by letters written while Tycho was steadily pursuing his observations at Hveen, supported by liberal emoluments and aided by numerous assistants and workmen, in this volume he is a traveller, seeking a new home in which to continue his work. We find him first at Rostock, then at Wandsbeck, afterwards at Benatky, and finally at Prague; and it is natural that his correspondence should be largely concerned with negotiations for reconcultation with his former patron the Danish king, or with the view of securing a new patron, such as he eventually found in the We have also the corre-Emperor Rudolf II. spondence relating to the equipment of the observatory at Benatky.

For the life of Tycho, these letters are most interesting. They have the further interest that they introduce us to Kepler, whose first letter to Tycho, accompanying a copy of his "Mysterium Cosmographicum," begins on p-14 of the volume, and whose last letter in October 1600 ends on p. 385. As the connexion thus established with Kepler was the most important, it might be said the only valuable result of Tycho's removal from Denmark, and as it resulted in the discovery of the laws of planetary motion, it is very gratifying to find this correspondence set in its place among Tycho's astronomical letters

The most interesting letters in this correspondence are perhaps Tycho's critique of the "Mysterium Cosmographicum" and the testimonial which Tycho gave Kepler in June 1600. Both have been published among the collected works of Kepler and are well known to students of the history of astronomy. In the former letter (pp. 44-46), Tycho, in the most courteous way. cast doubt on Kepler's theory of the connexion between the planetary spheres and the five regular solids, because it rested on Copernicus's values for the distances and eccentricities, which were seriously in error. He also objected to any doctrine of 'orbium realitas,' that is, to any reality of the spheres, and regarded the immense distance to which the Copernican hypothesis relegated the socalled eighth sphere, the sphere of the fixed stars. as an absurdity which by itself would destroy the whole theory. He suggested that Kepler should continue his line of study, including the eighth

sphere in his harmony, and invited his co-operation. In the same letter Tycho declared that the reason for his removal from Denmark was to prevent the destruction of his astronomical treasury collected through so many years with such great labour and expense. With our great store of observations it is difficult to realise the uniqueness of Tycho's work, so far exceeding anything that had survived from the ancient or that seemed likely to be attempted again in the modern world.

The editor, in addition to his usual brief but pertinent comments, has in this volume given us an alphabetical biographical index of the principal people named in the astronomical letters.

The twelfth and thirteenth volumes complete the collection of Tycho's observations. A flysheet issued with the last of these and dated 1926, Sept. 25, records how Dr. Dreyer before his death on Sept. 14 had requested the presidents of the Society of Danish Language and Letters to present this last volume of Tycho Brahe's treasury of observations to the Carlsberg Institute on Sept. 25, the fiftieth anniversary of its foundation, in gratitude for the munificence with which it had provided for the publication of the greater part of the works of the famous Danish astronomer.

The two volumes of observations contain not only Tycho's observations, but also several by Fabricius, and a few collected by Kepler There are also two catalogues of stars, but Tycho's complete catalogue appears elsewhere. Probably the most important part for present-day astronomy is to be found in the 107 pages devoted to observations of seven comets. These observations at least can never be superseded by observations of other comets made with better instruments.

### Our Bookshelf.

Artificial Fertilisers: their Chemistry, Manufacture and Application. By P. Parrish and A. Ogilvie. Vol 1 Pp. 356. (London . Ernest Benn, Ltd , 1927.) 45s. net.

As the authors state in their preface, this is the first English treatise on artificial fertilisers which deals in any detail with the technique of the manufacture of fertilisers. This, the first of two volumes, is almost entirely devoted to the manufacture of phosphatic manures, and the mixing and compounding of these with other fertiliser ingredients. After surveying in some detail the world's resources of phosphatic material, the mining operations are described in some detail.

The bulk of the book is taken up with the manufacture of superphosphate, by-products of other industries such as basic slag taking quite logically a minor share. Superphosphate manufacture in its

main outline has not changed since its invention, and improvements are due rather to engineering than to chemical progress, and modern plant and machinery are described and well illustrated by diagrams and photographs. The chemistry of the manufacture of soluble phosphates is dealt with briefly but adequately for the needs of the technician, although the statement on p. 31 that "phosphate rock is essentially tricalcium phosphate" is misleading and is contradicted later in the book. The chemistry of open-hearth basic slag is still obscure, but enough is said to indicate the problems before the investigator. A correct interpretation is given of the results in the citric solubility test for water-insoluble phosphate and, up to the present, no better measure of the availability of phosphate to the plant has been discovered.

This work comes at an opportune moment: the old-fashioned fertiliser industry in Great Britain has not only to face foreign competition in the export trade, but also attractive new compounds now being placed on the market by the great German fertiliser firms. In these, phosphoric acid functions as a carrier of ammonia and sometimes of potash also The superphosphate manufacturers of Great Britain are fully alive to this new aspect and the formation of the International Superphosphate Association is the result In a stimulating and thoughtful final chapter the trend of future developments is discussed. The authors conclude that superphosphate will be required for many years to come, but that only larger factories operating with highly efficient plant will be able to compete at all successfully.

Such a readable and well-illustrated book cannot fail to be of interest and service to all connected with the fertiliser trade, and the second volume will be awaited with interest.

The Practical Telephone Handbook and Gurde to the Telephonic Exchange. By Joseph Poole, and others Seventh edition, thoroughly revised and enlarged. Pp. xxv+870. (London: Sir Isaac Pitman and Sons, Ltd., 1927.) 18s. net

DURING the last few years the art of telephony has made gigantic strides and the future of the telephone industry seems very promising. Many engineers first acquired their working knowledge of the subject from the earlier editions of this wellknown handbook It has gradually increased in size, although much obsolete and obsolescent matter has been cut out in each edition In this latest edition the book has been increased by 146 pages and more than 100 illustrations. Although the book is becoming more technical and more mathematical, it can still be recommended for the beginner. The rapid progress of automatic telephony in Great Britain has taken even experts by surprise A few years ago it used to be urged that its secrecy, which is really one of its greatest advantages, laid it open to the practical joker who could play silly tricks with impunity. In the United States the trouble had proved to be a real one, and special laws were proposed to frighten the jokers. An unscrupulous business man also might cause the line of a rival to test 'engaged' at important times of the day. Luckily these defects have

been completely remedied

To scientific men the use that telephonists make of 'phantom circuits' to increase the number of conversations that can take place simultaneously between two stations always seems wonderful. The authoritative account of trans-Atlantic telephony given in this book will prove helpful to many. The saving of costs of trunk lines by means of thermionic valve repeaters is shown by the fact that in place of aerial lines weighing from 100 lb to 800 lb. per mile, there are now underground cables working between London and Glasgow and between London and Berlin weighing only about 20 lb per mile.

Linienspektren und periodisches System der Elemente. Von Dr. Friedrich Hund (Struktur der Materie in Einzeldarstellungen, herausgegeben von M. Born und J. Franck, Band 4.) Pp v1+ 221. (Berlin: Julius Springer, 1927.) 15 gold marks.

SINCE the work of Bohr, followed by that of Sommerfeld, Catalán, Heisenberg, and others, gave a theoretical foundation to spectroscopy, the analysis of the spectra of the elements on the basis of quantum mechanics has proceeded apace. The results are scattered through many journals, in many tongues. This material the author has collected and welded into a coherent account. The appropriate results of quantum analysis are quoted and their significance explained without the burden of mathematical proof The application of these results to the line spectra of the elements of the different columns of the Periodic Table is then fully discussed. Practical spectroscopists, chemists, and (may we whisper it) students of physics who wish to learn something of the methods and results of the new spectrum analysis, without first undertaking the formidable task of learning quantum mechanics, will welcome this well-written and informative account. For those who may wish to pursue the subject further, either on its more theoretical or on its experimental side, the author supplies a full and well-arranged bibliography of the literature of the subject, to the end of the year 1926.

Thermodynamics and Chemistry. By Prof. F. H. Macdougall. Second edition. Pp vii + 414. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd, 1926.) 27s. 6d. net.

The first edition of Prof. Macdougall's book was well received, and in the new edition the author has incorporated a considerable amount of new matter and has revised the old so that the work is considerably improved. The treatment is straightforward, with a free use of the calculus. The rather long section on phase rule diagrams is out of place, since there are separate text-books giving a better and more detailed treatment of this branch of the subject, which is more a matter for the drawing office than for the student of thermodynamics. The properties of electrolytes are dealt

with from the point of view of activity, and the Debye equation is used, although its detailed deduction is omitted. A good feature is the melusion of problems, but these are omitted in the last chapter on the quantum theory and Nernst's heat theorem. The number of books on chemical thermodynamics is not large, and Prof. Macdougall's is a useful member of the group. The only unsatisfactory feature of the book is its price, which is excessive, although that of the first edition was even higher.

South America an Economic and Regional Geography, with an Historical Chapter. By Dr E W Shanahan (Methuen's Geographical Series) Pp xiv + 318 (London: Methuen and Co., Ltd., 1927.) 14s. net.

DR SHANAHAN has succeeded in producing a book on South America that was much needed. After some preliminary chapters on the continent as a whole, including a most interesting one on historical geography, he treats South America by natural regions, thus avoiding much repetition which a

treatment by States would entail.

The book bears evidence of wide and discriminating reading, but it gives the impression of a compilation and lacks signs of personal acquaintance with South America Many of the broader human interests receive little notice, such as the immigration problems, the racial problems, and the character and peculiarities of the great cities and scaports. Cities are not merely market places; they have individualistics that are worthy of portraval even in a geographical work, if geography is to escape the charge of being merely the background of commerce But in spite of these criticisms we welcome the book, especially for its freedom from bias towards any particular interest or State, a defect which mars too many works on South America

An Introduction to Building Science By F. L. Brady. Pp. vni + 280 (London: Edward Arnold and Co., 1927.) 78 6d. net.

In a series of twenty-five chapters the author discusses his subject under the headings of physics and chemistry. His method is perspicuous and the diagrams deserve appreciative notice, as also the series of experiments and the lists of questions at the end of the successive chapters. They serve the useful purpose of testing the degree of know-

ledge acquired from the previous pages.

The use of constants for conversion from one thermometric scale to another is most unnecessarily condemned by Mr. Brady. He is, of course, not responsible for the double significance of the word calorie (distinguishable only by the employment of upper or lower case initial), but such duplication is unfortunate. If it be granted that "alloys are mixtures of metals," why call steel an alloy? It is no more an alloy than is wrought or cast iron, all three being dependent upon the proportion of contained carbon. Fig. 37 would be better were the comparative diagrams drawn to one scale. The book is, however, one to be accorded a hearty welcome.

# Letters to the Editor.

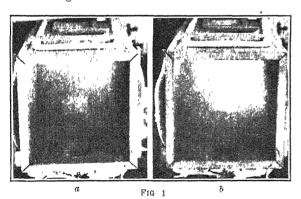

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. No notice is taken of anonymous communications.]

# The Magneto-optical Effect and a Correction.

This communication concerns the magneto-optical effect, described by me in Science (N.S. vol. 53, No. 1382, pp 565 to 569, June 24, 1921) and Nature, June 23, 1921, p 520, which was at that time a novel discovery or observation. The description was later followed by a statement of "Further Investigations" (Science, N.S. vol. 54, No. 1387, pp. 84-85, July 29, 1921)

In the first place I desire to make a correction in the latter communications, where it is stated that the "flickering observed appears to keep time with the cycles and not with the alternations of current." This is an error, as it was found later that the described fluctuations do follow the alternations, the mistake being due to misinformation as to the cyclic rate.

It may be desirable here to describe briefly the original phenomena, adding comments which relate to more recently observed facts. A magnetic field produced by a direct current, permanent magnet, or by interruptions or alternations of current, is rendered visible even when very weak, by a light smoke from an iron arc; such fume or smoke being effective for the purpose even when so thin or diffused as to be scarcely noticeable in the air Such smoke, diffused in the space where a field exists, when illuminated from above by sunlight or an artificial source and viewed in a direction across the light beam and more or less normal to the direction of the lines of force of the field, apparently becomes luminous, but in reality becomes a far better reflector diffuser in certain directions of the incident light than when the field lines are absent.

Viewed along the magnetic lines, no increased luminosity is produced even when the field is strong or the illumination strong, or both.

The condition for its observations seem to be.

(1) Illumination transverse (more or less) to the direction of the lines of the field.

(2) Viewing in a direction more or less transverse to the lines of the field and to the direction of the incident light

The amount of iron smoke in the air required to produce a very noticeable effect seems to be very small, although density of the smoke increases greatly the contrast between what is visible when current or field is on, and when no field exists. Indeed, without the presence of the field the smoke from the iron arc may be practically invisible. The illumination from

the smoke particles was found to be polarised as if produced by reflection from strings of fine particles, oriented in the direction of the field lines. These particles are exceedingly small, almost beyond ordinary high powers of the inicroscope, and the striated feiric oxide, which it seems to be, can be caught on a microscope slide while the magnetic field is on, and studied under high powers.

The remarkable thing is the small amount of the iron smoke needed to produce the effect and the instantaneous response to very weak fields. Thus, if an open coil or helix without a core of non be traversed.

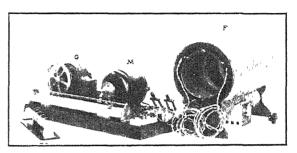

FIG. 2.

by a fluctuating or slowly alternating current, the flickering may be shown by a detector constituted by holding the open neck of a glass flask over an iron are for a few moments. Some of the smoke enters the flask, which can then be corked. Such a flask has shown flickering at a distance of twelve feet away from the small coil, through which a low frequency current was sent; and, curiously, when the flask was placed near the coil, the flickering was replaced by a steady illumination. When gradually removed from the coil in the direction of its axis, the flickering became more and more pronounced.

This indicates that the orientation, or arrangement of the particles to correspond with the field lines, takes place with a weak field, and almost instantaneously in a strong alternating field, in the latter case being accomplished and maintained throughout the whole wave of current. The zeros seem to be without effect in arresting the appearance, while at a considerable distance away from the same coil, excited as before, the weaker field at such a distance can only orient the particles at or near the maxima of the current waves. This seems to indicate that a certain very low value of the magnetising force is sufficient for the orientation or alignment of the particles. Retention of vision by the eye may also cover up any very short interruptions in the luminous effect itself.

Use has been made since the publication of the original descriptions of the effect for rendering visible to the eye a rotating field produced by biphase, three-phase, or polyphase currents. The effect is unique, and it can be photographed.

In the accompanying illustrations, Fig. 1,  $\alpha$ , shows a box with a glass front and back, a beam of light being sent in from the back with no excitation or magnetic field present; Fig. 1, b, shows the same with the coil lying flat on the top conveying current. In this case it is clear that a luminous effect, displaying the field of the coil has been depicted. In each case, of course, iron arc smoke has been within the box at each trial; it being allowed to enter through a hole at the bottom of the box seen indistinctly in the figures. It is surprising, too, how long a time it takes for the fumes to settle out of the air within the apparatus.

In Fig. 2 is shown a device for rendering visible a rotating field, such as that of a three-phase motor. The structure at F is, in fact, a field winding, clearly

showing in the photograph the three entering wires for its excitation. As the ordinary frequencies would be too high for observation, the rest of the figure to the left shows a small motor M driving at reduced speed a small generator G of the three-phase currents needed for the excitation of the field at F. Usual arrangements are provided for varying the speeds, and thus the cyclic rate or frequency of the currents in F. The interior of F is arranged with glass ends so that it may receive illumination from the back, and also that it may receive and retain iron arc smoke. In this way the revolving field inside the structure F becomes distinctly visible by a luminous glow revolving within it.

The direction of revolution may also be instantly changed by the switches provided for reversing two of the phases, and the speed of revolution of the field may be made slow, or so fast that retention of vision

results in a continued interior luminosity

It is probable that with further development, such arrangements may be designed to make use of this magneto-optical phenomenon in the study of distortions in alternating fields by the introduction of closed circuits in the form of rings, plates, and various forms of conductors, or even to compare the distortions produced by the material as well as the form of conductors in alternating fields. Perhaps, also, the distortions of field lines produced by revolving or moving conductors in even direct current fields may be exhibited or investigated. My time has not permitted much work, interesting as it may be, to be carried on.

Elihu Thomson.

July 5.

## The Origin of the Nebulium Spectrum.

In his letter to Nature of Oct. 1, p. 473. Mr. I. S. Bowen has made the important suggestion that several of the chief lines in the spectra of gaseous nebulæ may be due to what spectroscopists have called 'forbidden combinations of terms in the spectra of ionised nitrogen (NII), ionised oxygen (OII), and doublyionised oxygen (O III). It is, of course, no longer permissible to suppose the existence of hypothetical elements to account for the long-standing mysteries of nebular spectra, and we must accordingly regard the nebular lines as being produced by known elements under conditions of excitation which have not yet been imitated in the laboratory. It has seemed natural enough to look to the lighter elements, and those who, like myself, have given special attention to the spectra of these elements under widely varied conditions, have doubtless kept in view the possibility of finding some indications of nebular lines in the course of their observations. Extensive experiments, however, have failed to reveal any traces of them.

The evidence put forward by Mr. Bowen in favour of ionised oxygen and nitrogen is already very substantial and demands careful consideration. The case for O III is, in fact, a good deal stronger than appears from his letter. I have lately been investigating the structure of this spectrum, and it may be of interest to refer to some of the results obtained.

Doubly-ionised oxygen has six external electrons, and some of the more important configurations (in  $n_{\star}$  orbits), with the corresponding types of terms predicted by Hund's theory, are shown in the following table, the notation being that adopted in a recent paper on N II (*Proc. Roy. Soc.*, A, vol. 114, p. 662).

1.	2, 2,	3, 3, 3,		Terms
2 2 2	2 2 2 1 2 1 2 1	1 1 1	$\begin{array}{c} s^2p^2 \\ s^2p \cdot s \\ s^2p \cdot p \\ s^2p \cdot d \end{array}$	$\begin{array}{c} 1^{3}P_{210} \ 1^{1}D'_{2} \ 1^{1}S'_{9} \\ 1^{3}P'_{210} \ 1^{1}P'_{1} \\ 1^{3}D'_{321} \ 2^{3}P_{210} \ 1^{3}S'_{1} \ 2^{1}D'_{2} \ 1^{1}P'_{1} \ 2^{1}S'_{0} \\ 1^{3}F'_{432} \ 1^{3}D_{221} \ 1^{2}P''_{120} \ 1^{1}F'_{3} \ 1^{1}D_{2} \ 1^{1}P''_{11} \end{array}$

No. 3025, Vol. 1201

Without reference to the nebular lines, I have determined all of the terms on the second, third, and tourth rows, besides others, from my own (unpublished) observations. Utilising Bowen's observations in the extreme ultra-violet, the values of the three deepest terms follow as a matter of course, but are less accurate in consequence of the difficulties of measurement in this part of the spectrum. For the  $1^3P$  terms, Bowen has found  $1^3P_2 - 1^3P_1 - 193$ ,  $1^3P_1 - 1^3P_0 - 116$ , and the two green nebular lines are attributed by him to O III because of their separation  $\Delta r - 193$ . He thus identifies the nebular lines with the forbidden combinations  $1^3P_2 - 1^3D'_2$  and  $1^3P_1 - 1^3D'_2$ , but, the value of  $1^3D'_2$  being then undetermined, he gives no additional evidence in support of this view.

From singlet combinations in the extreme ultraviolet previously suggested by Bowen (*Phys. Rev.*, vol. 29, p. 241), in combination with the values of  ${}^{1}P_{1}'$  and  ${}^{1}P'''$  since determined by myself, it is readily found that  ${}^{1}D'_{2}$  - 424385, and  ${}^{1}S'_{0}$  = 401472. For the nebular lines, on Bowen's view, we thus have

The assumption as to the nebular origins in question can be tested by the lines  $\lambda 305.7$  and  $\lambda 374.3$  previously suggested by Bowen as probably representing the regular combinations  $1^3P - 1^3P$  and  $1^3P - 1^3P'$  respectively, using the values for  $1^3D$  and  $1^3P'$  which I have determined. Unfortunately, each of these combinations yields six components, which cover but 0.29 Å in the first multiplet and 0.36 Å in the second, and so have not been resolved. However, the calculated wave-numbers for  $1^3P - 1^3D$  range from 326986 to 327295, and compare very favourably with the observed line  $\lambda 305.7$ , for which  $\nu = 327118$ . Similarly, the lines  $1^3P - 1^3P'''$  range from 267134 to 267584, and are in good agreement with 267165 representing the observed line  $\lambda 374.3$ . These considerations appear to give strong support to the view that the two green lines of the nebulae are due to O III, but no further tests appear to be available at present.

The agreement in position of the nebular line  $\lambda 4363.21$  with the combination  $1^4S'_0 - 1^4D'_2$  of O III is as close as can be expected, and further tests would seem to depend upon the possibility of measurements of lines in the extreme ultra-violet and in nebulae with a still higher order of accuracy.

The evidence for attributing the nebular lines λ6583 6, λ6584·1 to N II appears to be very convincing, but the published observations of the N II spectrum in the extreme ultra-violet are inadequate

to provide further tests.

Bowen's assignment of the strong nebular lines  $\lambda 3728.91$ ,  $\lambda 3726.16$  to O II leads to term values for  $1^2D_{32}$  of the expected order of magnitude, and the consequent calculation of the red line  $\lambda 7325$  may be provisionally considered to support the suggested identifications. Owing to the apparent absence of regular intercombinations of doublet and quartet terms, however, the only test at present available would seem to be the discovery of one or more companions to the nebular line  $\lambda 7325$ . If the identifications be correct, there should be a satellite about 10 A distant on the less refrangible side of this line, and a 'second chief' line in a position which cannot be predicted because the separation of the  ${}^2P'_2$  terms has not yet been determined.

The numerical evidence, on the whole, thus appears to be in favour of Mr. Bowen's suggestions, and it is interesting to note that if these should be fully

confirmed, the observations of nebulæ may be used to determine the structure and exact positions of certain unresolved lines in the extreme ultra-violet

A FOWLER

Imperial College of Science, South Kensington, S.W.7, Oct. 14.

#### The Rare Earths.

In searching for evidence that would enable a decision to be made as to the exact distribution of the electrons responsible for the series of fifteen 'rare earth' elements from lanthanum to lutecium, the colour of their salts appears to be of prime importance, particularly as it is known that colour is intimately associated with movements of electrons in atoms. The fact that many of the rare earths yield coloured salts has led to considerable uncertainty as to their proper place in the periodic classification, and many attempts have been made to allocate them to appropriate periodic groups on the grounds of valency, isomorphism, and colour analogies.

I have recently shown (Jour. Chem Soc., Sept. 1927) that the foregoing fifteen rare earth elements are all analogues of scandium, the last fourteen of them forming an anomalous subseries of the transition subperiod of the third long period of the classification. This arrangement rules out any possibility of allocating these elements to more than one periodic group. It follows, in consequence, that the rare earths have no real relation to any other series of elements and that the observed colour resemblances are fortuitous.

Examination of the colours of the salts of these elements from this new viewpoint has brought to light colour sequences hitherto unrecognised, the sequence of colours of the salts of the first eight rare earths being identical with that of the last eight in reverse order. Lanthanum, cerium, praseodymium, needymium, illinium, samarium, europium, and gadolinium salts are colourless, colourless, green, red, unknown, yellow, faint rose, and colourless respectively, while those of lutecium, ytterbium, thulium, erbium, holmium, dysprosium, terbium, and gadolinium show the same colour sequence, with the apparent exceptions of terbium and holmium.

The salts of terbium, the 7th member of the 2nd series, are recorded as colourless, but in thick layers they are almost certainly faintly rose, for they exhibit absorption at the blue end of the spectrum. Terbium is thus analogous to europium, the 7th member of the 1st series, the salts of which are either faintly rose or colourless and exhibit absorption mainly at the blue end of the spectrum.

The salts of holmium, the 5th member of the 2nd series, are known to be yellow, whereas the salts of the recently discovered element illinium, the 5th member of the 1st series, are as yet unknown. From the duplicate colour sequence, however, it may be predicted with confidence that illinium salts when obtained will be yellow like those of holmium. The yellow colour predicted for illinium salts may partly explain why illinium was not sooner detected in the intensive researches on rare earth separations of the last century, for samarium, with which it is naturally associated, is nearest in atomic weight, yields yellow salts, and probably exhibits absorption in the same spectral region.

As the duplicate colour sequence shown in the following table relates to the trivalent ions of the elements, the numbers in the 1st column are the

actual numbers of electrons in the ions (3 less than the atomic numbers)

51 La,	68 Lu	colourless	0,	14	0		(0, 0),	(6, 8)
55 Ce,	67 Yb	,,	1,	13	+1,	-1	(1, 0),	(6, 7)
56 Pr.	66 Tm	green	2,	12	+2,	-2	(2, 0),	(6, 6)
57 Nd.	65 E1	red	3,	11	+3,	- 3	(3, 0),	(6, 5)
58 11,	64 Ho	yellow	4,	10	+4,	4	(4, 0),	(6, 4)
59 Sa.	63 Dy	,,	5,	9	+5	- 5	(5, 0),	(6, 3)
60 Eu,	62 Tb	faint rose	6,	8	+6,	- 6	(6, 0),	(6, 2)
61.6	h£	colourless	1 1	7	+	7	(6.	1)

In the 3rd column are shown the numbers of electrons in the ions after deducting the 54 of the La ion (xenon structure). The 4th column shows the variation of these electrons from 0 and 14, cerium for example having 1 electron and ytterbium -1 (1 less than 14). The identity in the colour sequences indicates that the same colour is obtained in two different ions when one has as many electrons more than zero as the other has less than 14.

There being only two colour sequences, it may be regarded as certain that the 14 electrons concerned are arranged in only two sets or subgroups. Further, as gadolimium is the only element common to both sequences, being the last of the first sequence and the first of the reversed sequence, it may be inferred not only that gadolimium has electrons in both subgroups, but also that the second subgroup begins when the first is complete. As gadolimium has 7 electrons and lutecium 14, it follows that the former has the subgroup structure 6, 1, and the latter 6, 8. The complete distribution of the 14 electrons in the rare earth elements is given in the last column of the table.

It can be no more than a curious coincidence that the number of electrons in each ion from gadolinium to lutecium is expressed by the same figures as the numbers of electrons in the two subgroups, the gadolinium ion, for example, having 61 electrons and the subgroup structure 6, I.

In Bohr's theory of atomic structure, the maximum number of subgroups in a quantum level is equal to the quantum number, and the maximum number of electrons in a subgroup is equal to twice the quantum number. In the 4-quanta level there should thus be 4 subgroups of 8 electrons each, this structure being attained in lutecium by the increase of 3 subgroups of 6 each to 4 of 8 each, thus involving four types of subgroup change though only two types of change are evident from the duplicate colour sequence.

Early in 1924 I pointed out that the experimental facts of emission and absorption X-ray spectra indicated a number of quantum subgroups invariably greater than is given by Bohr's rule. The intensities of the emission lines and the widths of the absorption bands further indicated that the numbers of electrons in subgroups could not be equal, evident also from the fact that the number of subgroups in a level is always an odd number, while the total number of electrons m a level is always an even number. I deduced that the 4-quanta level must contain 7 subgroups of 2, 2, 4, 4, 6, 6, 8 electrons, and suggested a new law of uniform atomic plan that the maximum number of subgroups in a quantum level is equal to one less than twice the quantum number, and that the maximum numbers of electrons in subgroups is equal to twice the natural numbers taken in duplicate, the last and largest subgroup being unduplicated and equal to twice the quantum number. This law was supported by relevant chemical evidence, and has since been confirmed by Stoner's work on spectral multiplicity. The foregoing electronic structures for the rare earth elements, as deduced from the duplicate colour sequence, fully confirm the law of uniform atomic plan, the subgroups for the 4-quanta level being 7 in number and consisting of 2, 2, 4, 4, 6, 6, 8 electrons as in lutecium.

The arrangement of the rare earths into the fore-

<sup>&</sup>lt;sup>1</sup> Hopkins, in "Chemistry of the Rarer Elements," p 107, gives the colour of dysprosium salts as "bright green." This is an error, all being in fact golden yellow.

going two series accords completely with their analytical separation into two groups, the cerium earths lighter and the 'yttrium' earths heavier than gadolinium. Details of the division of the lare earths into the two series on other chemical and crystallographic grounds will shortly be submitted to the Chemical Society.

# The Films Responsible for Oxidation Tints on

The colours produced by heating metals in air have long attracted interest. Within the last three years it has proved possible in two cases (lead and iron) to separate from the basis metal the oxide-films responsible for these tints. In the case of lead, which is liquid at the requisite temperatures, the oxide-film is lifted off the molten metal on glass (*Proc. Roy Soc.* A, 107, 228, 1925), whilst in the case of iron the method employed is that originally worked out for the isolation of the much thinner, invisible skin responsible for the passivity of iron treated with oxidising agents. This method (*Jour Chem. Soc.*, 1020; 1927) consists in undermining the oxide-film by dissolving away the metal below it with iodine solution, so that the film comes peeling off in cuiling fragments, which can be washed by decantation and examined under the microscope

The chemical aspects of the matter have been discussed in the two papers quoted above, but there are certain physical observations which may perhaps deserve to be put on record. There is a remarkable difference between the oxide-films stripped from lead and iron respectively. The lead oxide film is highly transparent, and the film itself, when separated from the metal, shows interference colours, depending on the thickness, the tint by reflected light being always complementary to the tint by transmitted light. As a result of the transparency, the higher order colours corresponding to thick films can easily be observed, the second-order tints being as vivid as the first-order colours; at greater thicknesses third and fourth orders The sequence of tints is essentially the same as that exhibited by silver exposed to iodine vapour, silver iodide also being a transparent substance

When we come to iron, however, the state of affairs is different. Viewed by reflected light, the film fragments show a brilliant metallic lustre, and in some cases might easily be mistaken for metallic iron; they retain all the surface irregularities displayed by the original metallic surface before its conversion into oxide; thus if the abrasive treatment originally used to produce a clean metallic surface has left a series of microscopic grooves and ridges on the metal, the films are crenulated in a manner which faithfully reproduces these grooves and ridges. However, on altering the illumination so that the films are viewed by transmitted light, it is at once seen that they consist of a transparent substance, with only occasional opaque points consisting mainly of minute spots of residual metallic iron embedded in the oxide and usually arranged in lines following the grooving (these particles of residual iron are best shown up as expanding blue spots by treating the film fragments with an acid solution of potassium ferricyanide). But the transparency of the oxide films is distinctly less perfect than that of the corresponding lead oxide films: even the film responsible for the first-order yellow tint has a perceptible yellowish-grey colour, clearly due to specific absorption, whilst the films become darker and darker as we proceed along the sequence, so that the films to which the second-order tints are attributable show a quite dark brownishgrey appearance by transmitted light.

This specific absorption is more than sufficient to mask any colour due to interference, and consequently the films—unlike those separated from heated lead do not themselves show bright tints, although the character' of the brown colour varies slightly with the thickness—possibly as the result of interference of the 'thin-film type' It may perhaps seem curious that the films should nevertheless produce colours when in contact with the metal. In my opinion an explanation can be given. Any theory based on interference between the light reflected respectively from the outer and inner surfaces of the film would lead us to expect that a slight degree of opacity will, at low film thicknesses, actually favour the production of colour, since it will tend to reduce the inequality between the intensity of the two reflections. when, however, the film is off the metal, the two reflections would be approximately equal in intensity in the case of a highly transparent film, and the slightest opacity will be unfavourable to the effect The serious opacity of the thicker films of iron oxide explains why the second and third order tints—so conspicuous in the case of lead—are badly developed on iron, even when the film is still on the metal. After the end of the first-order tints, the colours become faint and are modified somewhat by the specific colour of the scale, which, although slightly yellowish by transmitted light, is a rather bluish grey by reflected light. Nevertheless, there has been no difficulty in tracing the sequence as far as the thirdorder red, the sequence being essentially the same as that shown by lead or copper.

### Adsorption of Gases on the Surface of Mercury.

CERTAIN methods of measuring the surface tension of mercury, especially the 'big drop' method as used by Popesco (Am. de Physique, 3, p. 402, 1925), appear to show that the presence of an or other gas mercases the surface tension of a freshly formed surface by about 100 dynes. The 'drop weight' method, on the other hand, shows a difference of only a few dynes between the values in air and macuo, and this indeed in the opposite sense to that indicated above (Harkins, Jour. Am. Chem. Soc., Dec. 1920). Observations by the writers using the same mercury in order to measure its surface tension by the above as well as other methods show that the differences in the measured values of the surface tension are due to differences in the method and not to differences in the quality of mercury (Trans. Faraday Soc., May 1927).

It is therefore especially important to gain some information as to the adsorption of gas by a freshly formed mercury surface. This has now been accomplished by applying to gases a method similar to that used by Schofield for solutions (Phil. May., Mar. 1926) A shower of about 500 drops per second of mercury falls down a vertical tube about 50 cm. long to the middle of which is sealed a side-tube. Through this side-tube is fed a slow stream of either hydrogen or argon containing a small percentage of carbon dioxide. The stream of gas divides and is taken from the vertical tube by two outlets, one near the top and the other near the mercury surface at the bottom of the tube. From these outlets the gas passes to the tubes of a Rayleigh interforometer.

Any gas adsorbed by the falling drops is given up at the bottom of the tube, and if the carbon dioxide

is selectively adsorbed, this will cause an increase in its concentration in the lower tube and a corresponding decrease in the upper tube By counting the drops and measuring the volume of mercury passing each second, the area of surface can be estimated, while the concentration change indicated by the interferometer and a knowledge of the rate of flow of the gas enable the amount adsorbed per unit area to be calculated Measurements indicate that for concentrations of 5, 10, and 15 per cent, carbon dioxide in either hydrogen or argon, approximately a complete monomolecular layer of carbon dioxide is adsorbed within one-fifth of a second after the surface is formed At a concentration of one-half per cent. the adsorption appears to be definitely less, and at fifty per cent. definitely more, than is accounted for by a monomolecular layer

Later it is hoped to publish a detailed account of the work, together with measurements of surface tension of both the 'big-drop' and 'drop-weight' methods of surfaces formed in similar mixtures of gases. Measurements of the weights of mercury drops falling from tubes wetted by the mercury (amalgamated platinum or copper) in general yield greater values for drops formed in air than for those formed in vacuo, so it seems at least possible that the 'drop-weight' method of measuring surface tension gives different values according to whether the liquid does or does not wet the tube.

inquid does or does not wet the tube. M L. OLIPHANT R S. BURDON.

## Periodicity of Molecular Numbers.

I BELIEVE the following facts will serve a purpose in disclosing a new molecular structure principle. Construct a table as follows:

$\boldsymbol{A}$	B	C	D
Minimum	Marine Marine	0	2
4	6	8	10
12	14	16	18
20	22	24	26
28	30	etc.	etc.

Let these figures represent molecular numbers (total atomic numbers) of compounds containing no elements beyond scandium. The distribution of mole-

cular numbers of certain classes of substances among these four groups reveals a marked preponderance of one group and a corresponding deficiency towards another. The diagram (Fig. 1) indicates the percentage of occurrence, in each group, of the following sets of compounds (1) 244 gases having b p 100° C. or below, (2) 57 inorganic acids, (3) 24 most familiar bases, (4) a random set of 60 ions where a unit was added to or subtracted from the total atomic numbers of each for every negative or positive charge respectively.

The striking contrast between the curves of acids and bases is significant, as well as the similarity between those of gases and ions. There is the following connexion between my table and isometric polyhedrons, on the grounds that atomic numbers represent fundamental units which tend to occur in pairs: a pair on each face of a cube, or of combinations thereof, produce numbers of group A, or of group Bif a pair be assumed in the centre of the configuration as well; a pair on each face of any isometric solid, excepting those just mentioned, will give a number of group C, or of group D if a pair be also assigned to the centre It may be stated that the properties of ions and molecules are periodic functions of their molecular numbers, under certain restrictions, and it must not be overlooked that we are now considering only the first 21 elements of the periodic system, for reasons which cannot be discussed here

# Critical Potentials of Copper by Electron Impacts.

THE following method has been used successfully in the determination of some of the critical potentials of copper by electron impact. Essentially the method is the ordinary three electrode one in which an equipotential source of electrons, a gauze, and a receiving electrode are used. The gauze in this case was made of a copper strip 0 025 mm, thick, through which holes were bored. This gauze was heated electrically and served as a source of copper vapour, the electrons being accelerated to it at the same time.

The critical potentials observed, together with the values calculated from the spectroscopic data given by L. A. Sommer ( $Zeit.\ f\ Phys.,\ p\ 711,\ Nov.\ 1926$ ), are as follows .

State of Atom.	Observed voits	Sommer's value
Ionised .	. 77	7.69
$^{2}D_{3}$ , $^{2}D_{2}$	1 61	1.38, 1.64
$2^{2}P_{1}, 2^{2}P_{2}$	. 3.80	3.77, 3.80
$^4P_3$	4 84	4.87
$^{2}D_{3}^{^{-}}$ .	5.65	5 75
$3^2P_1$	6.08	6.09
$3^{2}S_{1}, D$	6.73	6.52, 6.75
${}^{2}D_{3}^{2}$ .	8 26	8 28
$^{2}G_{5}$	8.73	8.73
${}^{2}P_{1}^{'}$	. 9.40	9 27
•••	. 10.07	10.01
Ionised .	10.91	10.90

One other critical potential observed at 26 volts corresponds to no spectroscopic transition and may

possibly be due to an impurity.

The question might be raised whether the value of 9.4 volts might not correspond to an ionisation from the metastable D state. This would require 9.52 volts. This does not seem probable, however, as it would require two electron impacts. On account of the low vapour density available and small electron current, any effect depending on two electron impacts would be too slight to be noticeable.

The method is being applied to other metals.

## Mud Volcanoes of Minbu, Upper Burma.

The accompanying photographs of the mud volcanoes of Minbu in Upper Burna may be of interest to readers of Nature Minbu is on the Irrawaddy, near the oil-fields of Yenangyaung. The volcanoes are small hillocks of grey mud or clay. The hills begin as holes, from which mud oozes and forms continually growing cones Inflammable gases are also exuded with the mud The local people associate superstitious ideas with the volcanic activity

Fig. 1 is a general view of the mud volcanoes. Fig.

Fig 1 -Mud volcanoes at Minbu

2 shows instantaneous stages of bubbles of mud in the crater of the largest volcano. The crater is about 5 ft. across; and the bubbles in Fig. 2 were about

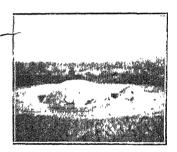

Fig. 2.—Stages in bubble formation.

1½ ft. in diameter. The mud is thick, but cold, with a faint odour suggestive of crude petroleum.

# Flame and Combustion.

WE want to thank Prof Armstrong for his breezy review of our book in NATURE of Sept. 24 and his suggestions for improving our brains Before putting on the 'thinking cap,' however, we would like to ask him why, in discussing flame-reactions, he asserts that we "ignore the prime fact, that the heat of combustion of carbonic oxide is below that of hydrogen; . . It cannot, therefore, he oxidised by steam For, in our 'nursely' days, we were taught that it is the other way round, and that, volume for volume, hydrogen burning to steam gives out about 16 per cent. less energy than carbonic oxide burning to carbon dioxide; also that the change from the system  $CO + H_2O$  (steam) to the system  $CO_2 + H_2$  is exothermic. If, as Prof. Armstrong says, we are wrong, we have sinned in such good company as Berthelot, Julius Thomsen, and indeed every other investigator of heats of combustion On the other hand, if we are right, does not the 'snag' in his combustion theory thus stand self-revealed? Is there, indeed, any evidence that not 'hydrone' (steam) but something much more complex and 'hydronolie' (water) is formed in flames?

Doubtless Prot. Armstrong will dismiss all this as of no consequence, as he does our spectroscopic evidence, namely, that the flame spectra of dry CO-air explosions at high initial pressures show no vestiges of 'steam lines'. We regard it as conclusive against his theory. Such being the case, we do not wonder that he wants our laboratories to be shut up whilst he settles the matter for us intellectually.

WILLIAM A. BONE D. T. A. TOWNEND.

- The heats of formation given by Thomsen are.

 $H_2$ , O = 68360 CO, O = 67960

I take into account the heat of formation of water, not that of hydrone (steam), between which there is a protound difference—Prof. Bone already has kindly given me credit for carrying my imagination far in these matters: I would ask him to try to follow me ere we begin to dispute.

H. E. Armstrong.

# High-Frequency Interruption of Light.

At my suggestion, Messrs, Adam Hilger and Co. have made the experiment of passing a beam of light through a quartz piezo-electric resonator placed between crossed Nicol prisms.

When the crystal plate is excited to resonant vibration by an applied oscillating voltage from a valve-circuit, light is strongly transmitted, and examination of this light in a rotating mirror shows that it consists of regular flashes, the frequency being apparently double that of the electrical oscillations. The effect is best obtained when the light is passed in a direction parallel to that of the optic axis or, to avoid rotatory dispersion of white light, at an angle of 22°½ with this axis. An attempt to photograph the flashes passing through a crystal oscillating at 144 kilocycles per second on a high-speed film camera was unsuccessful, but faint striae were obtained on a plate moved slowly across the beam after resolution

Any bright source of light may be used, the colour of the flashes of light from a white source changing, however, as either Nicol is rotated. With monochromatic light the interruption is probably complete.

It would seem probable that the high frequency and perfect regularity of the flashes there seems no reason why ten million per second, or more, should not be possible render this method superior to all others, such as the toothed wheel of Fizeau, the rotating mirror of Foucault, or even the so-called 'Kerr' cell recently employed for television - which have hitherto been used to obtain rapid intermittence in a beam of light.

The application to a variety of physical determinations such as the measurement of light-velocity, exact comparison or even absolute determination of crystal frequencies, production of a time-base on a moving film, etc., is obvious, and the method may also prove valuable in telegraphic transmission of pictures and in the photophone. The intensity of the flashes can readily be modulated by modulating the oscillating voltage applied to the crystal.

I wish to thank the management of Messrs. Adam Hilger and Co. for so kindly giving facilities for the experiments, and Messrs. Underfull and Brown of their staff for the interest and skill which made the demonstration of them a success.

Kerr Grant.

# Clustering and Periodicity of Earthquakes.

By Dr. CHARLES DAVISON.

I VERY few years we pass through a season of marked earthquake-frequency, or, as Mallet called it, a 'period of paroxysmal energy' In the mere fact of clustering, there is nothing remarkable, it is its intensity, rather than its existence, that is worthy of notice In Italy, for example, as Mercalli pointed out, 209 destructive earthquakes occurred between the years 1601 and 1881, and 182 of them in 103 years <sup>1</sup> In other words, the average frequency of great earthquakes during one of the cluster-years was eleven times that

during one of the remaining years

The first seismologist who examined the clustering of carthquakes, the first, indeed, who possessed the necessary materials, was Robert Mallet 1858 he drew curves representing the frequency of earthquakes in each year from 1500 to 1850 The intervals between successive maxima in these curves varied widely Though he could trace no law in their variation—it should be remembered that he counted weak shocks as well as strongtheir average duration was found to he between five and ten years, the shorter intervals being those of fewer, and usually weaker, earthquakes <sup>2</sup>

Fifty years later, John Milne went close to the heart of the problem by suggesting that variations of seismic activity in distant regions may be synchronous. Considering the earthquakes from 1899 to 1907, he noticed that, during the last six years, the annual numbers of 'large earthquakes' on the eastern and western sides of the Pacific rose and fell together In the following year he found that the destructive earthquakes of Italy and Japan during the last three centuries occurred in periods of activity, the intervals between them ranging from five to twenty years, and that, of the eighteen years of maximum frequency in Italy, fourteen agreed with years of similar activity in Japan "These coincidences suggest," he says, "that a relief of seismic strain in one part of the world either brings about a relief in some other part, or that relief is governed by some general internal or external agency "3

At this time, Milne's catalogue of more than 4000 destructive earthquakes was still unpublished, though it must have been approaching completion. It is on the fuller portion of this great work—that relating to the northern hemisphere from 1750 (and for some purposes from 1701) to 1899—that the present inquiry is based. My object at first was merely to ascertain if the cluster-years for different intensities were the same or in any way related, and this work led to the recognition of several periods in the recurrence of cluster-years. I hope to give fuller details of these periods in a

later paper.

To each earthquake Milne assigned an intensity

1 (4 Mercalli, "Vulcani e fenomeni vulcanici in Italia," 1883,

No. 3025, Vol 120]

according to a scale of three degrees Shocks of intensity I. were strong enough to crack walls or chimneys or to shatter old buildings By those of intensity II, buildings were unroofed or shattered and some were thrown down. Earthquakes of intensity III. destroyed towns and desolated districts In order to smooth away minor inequalities, I have taken three-yearly means of the annual numbers of earthquakes of each intensity The corresponding curves show definite years of clustering, which are given in the following table:

			Int III	Int II	Int I	Sunspot Minimum
A B			1754–56 1765–66	1755–56 1767	$1755-56 \\ 1766-67 \\ 1771-73$	1755 1766 1775
C			1785–90	$\begin{pmatrix} 1784 - 86 \\ 1789 - 91 \end{pmatrix}$	1771-73 17785-86 17791-92 1799-1800	1775 1785
D E F			1810-11 1822-23	1811 1818–20	$^{1811-13}_{1821-22}$	1810 1823
G		•	1828-29 $1834-36$ $1840-41$	1827 1832 1840–42	1827–29 1840–42	1833 1843
H			1845–47 1852–57	1846-48 1852-56 1859-60	1846-47 1852-57 1861-63	1856
K	•	٠	1868-72	1869-72	1867 1873-74 1880-81	1867
L M	:	٠	1884-86 1892-93	1884 1893–94	1885–86 1895	1889

It will be seen that, in all three classes, there are twelve clusters at approximately the same times. They are denoted by the letters A-M <sup>5</sup> There are also six other clusters, two common to two classes, and four of earthquakes of intensity I. only. Of the latter, two may not be real exceptions, for in the other classes there are traces, too slight to be otherwise noticed, of clusters about the years 1773 and 1798. In any case, the existence of at least four of these additional clusters seems to imply that they are not consequences of the great shocks of intensity III., but rather that the clusters of all classes are the effects of some common cause or

More important, however, than the coincidences of the clusters are the intervals between the years of maximum frequency. Some of the intervals are so suggestive of an eleven-year period that it was only natural that the cluster-years should be compared with the turning epochs of sunspot frequency. The last column of the table shows that eight clusters in all three classes (A-E, G-K) agree closely with the years of low sunspot frequency, and that this correspondence also holds for three other clusters (1771-73, 1799-1800, and 1832 or 1834–36) which appear in only one or two classes. The only divergences are for the last two years of sunspot minima.

pp 353-355 2 Brit Ass Rep., 1858, p 49 and plates 1-6. 3 Brit Ass. Rep., 1908, pp. 63-64, 1909, pp 56-58 4 Brit Ass Rep., 1911, pp 649-740.

<sup>&</sup>lt;sup>5</sup> The date of the maximum epoch M may be too early, for, towards the end of the century, the catalogue may not be quite complete.

In order to test more closely the existence of an eleven-year periodicity, I counted the numbers of earthquakes of each intensity in the years 1755, 1766, . . , 1887, 1756, 1767, . . , 1888, and so on, and took five-yearly means of these eleven sums, with the following results, the first subsequent year of least sunspot frequency being 1765:

Intensity	Fust Maximum Epoch	Amplitude		
III	1764 1762–63 1763–64	0 16 0 12 0 09		

Thus, in destructive earthquakes of every intensity, the maximum-epoch of the eleven-year period occurs shortly before the epoch of least sunspot frequency, and the amplitude increases with the intensity of the shock. It may be added that the epochs are almost exactly the same for the same three classes for the separate intervals 1701–99 and 1801–99, and for all three intensities together for the interval 1501–1698, and for each season of the interval 1701–1898.

It is interesting to notice that the same periodicity holds in widely separated regions. Taking the three intensities together, the maximum occurs in 1764 in Europe, in 1763-64 in Asia, in 1764 in

Italy, in 1764-65 in China, and in 1763-64 in the island groups of the western Pacific. Even in the slight earthquakes of Great Britain, the same period is present with its maximum in 1763-64. Thus, by a somewhat different line of evidence, Milne's remarkable generalisation seems to be confirmed.

In addition to the eleven-year period of destructive earthquakes, there are other clearly marked periods of 19, 22, and 33 years, the maximum epochs of which (1754, 1760, and 1757) agree closely in widely distant regions of the northern hemisphere. Some of these maxima seem to be responsible for clusters in the above table, especially for those of the years 1791, 1847-48, 1880-81, and about 1887. To the occurrence of their minima about the years 1798, 1833, and 1878, the absence or slightness of clusters is probably due.

During the present century, the maxima of the 11, 33 and 19 year periods occurred in 1918, 1922 and 1925, those of the 11, 22 and 33 year periods are due in 1951, 1958 and 1955, and those of the 11, 22, 33 and 19 year periods in 1984, 1980, 1988 and 1982. The times of unusually frequent earthquakes are thus, 1918-25, 1951-58 and, especially, 1980-88. The first of these intervals is notable for its very numerous earthquakes, some of which, such as the Chinese earthquake of 1920 and the Japanese earthquake of 1923, were of great violence

# Invention as a Link in Scientific and Economic Progress.1

By Sir James B. Henderson.

INVENTION forms the natural link between physics, chemistry, and engineering, and every advance m one or other of these produces a reflex action on the other. For example, a discovery in physics which increases accuracy of measurement by providing an indicator more sensitive than any previously known, is soon embodied in an engineering instrument carefully designed and manufactured for sale at a price which makes it available to every physicist for use in further research. Thus modern research in physics and chemistry is carried out with accurate apparatus which would be available only at a prohibitive price if it had been made for the particular research alone. The assemblage of apparatus used in a modern research is sometimes like an engineering installation, and is in marked contrast with the cruder, home-made apparatus, designed ad hoc, which was common a generation ago.

The closer the intercourse between the physicist, the chemist, and the engineer, the greater will be the fertility in invention and the faster the economic progress. The physicist working continually in a laboratory where everything is specially designed to facilitate accuracy of measurement and to eliminate disturbance, is apt to forget how artificial his working conditions really are, and that before any of his beautiful experiments can have

a practical application in industry a great deal of invention is required.

As an example of successful invention involving an accurate measurement to be made under practical conditions unsuitable to accuracy, I may cite the Barr and Stroud range-finder, which was invented by two young professors in the Yorkshire College, Leeds. The problem consisted in measuring with great accuracy, say to a second of arc, the small angle subtended at a distant target by a short fixed base placed at the observer. At the time when this invention was made, some forty years ago, the only scientist who normally measured angles to seconds of arc was the astronomer with his large telescopes mounted on great concrete foundations, with graduated circles from three to six feet in diameter and microscopes to read the scales. It seemed, therefore, impossible to contemplate the measurement of angles with anything like equal accuracy on board a rolling ship and with no expert operator.

Yet the two inventors, seeing an advertisement in the pages of *Engineering* announcing competitive trials of range-finders to be held by the War Office, took this seemingly impossible task in hand There was little time to spare. The first instrument was designed in outline in a week, and much of the subsequent success is attributable to the sound physical principles underlying this

<sup>1</sup> Continued from p. 553.

No. 3025, Vol. 1207

design and to the very ingenious design of all the constructional details, due to the happy combination of an engineer and a physicist, both of whom were men of imagination with a flair for invention. Their range-finder was constructed in the College buildings and, to indicate the amount of time that was available, the final adjustment of the instrument was made on a star from the railway platform at Rugby on the way to the trials at Aldershot

During the trials the instrument worked well at first, but after the sun came out it commenced to read 'as thousands of yards ranges which were palpably a few hundred 'and the inventors dis-covered that their beautiful angle measurer was also a thermometer and a sunshme recorder combined They were not surprised to have it rejected, and they might actually have abandoned it entirely if they had not been asked by the Admiralty some time later to submit an instrument Then followed ten years of most for naval use patient struggle against physical and engineering difficulties, not to mention financial difficulties, for the inventors acted as their own promoters and the financial side of the business must have taxed their resources to the utmost But at last they succeeded, and their range-finder is now the standard instrument in the British Army and Navy, and in other countries as well, and has been the foundation of one of the best firms of scientific instrument makers in the country As student or as assistant I had the honour to serve under both Prof Barr and Prof Stroud, both of them great teachers, versatile inventors, and most lovable men, and I am happy to be able to pay this small tribute to them and to their great achievement.

# THE DIFFICULTIES OF INVENTION AND THEIR REMEDY.

I wish it to be understood that where I have used the word 'invention' I am dealing with the great inventions, and not with the thousand and one minor and comparatively unimportant, though useful, inventions which flood the Patent Office every year. The latter are generally simple affairs, a minor improvement in a known mechanism or a new way of performing an old simple I do not wish to belittle these minor inventions in any way. They serve their purpose in our everyday lives, and all are traceable more or less directly to some major invention of the past, but the distinction which I wish to draw is that in very few cases is their manufacture or development a matter of difficulty I am therefore dealing solely with the big inventions and their development, and it is to the question of the obstacles that are too often encountered in their development that I wish to draw particular attention I wish now to examine the question of how to eliminate, or at least minimise, these difficulties that obstruct the inventor and so retard the march of progress.

The first way that suggests itself to me is by means of education. Our educational policy in schools on the scientific side deals with physical

laws as facts, and the teacher generally deals only with phenomena with which he can afford to be dogmatic and ignores the enormously greater range of phenomena about which science knows little or nothing This system inevitably breeds in the student and in the general public the impression that Nature acts according to certain definite laws and that there is nothing about these laws which is not known to science In actual fact, the more the scientist knows about these laws the more he is impressed with his ignorance and the failure of science to fathom the complexity of Nature. Much of the misunderstanding of invention and its difficulties is due to this method of teaching, and will endure so long as this method is maintained If it were possible to teach physical and chemical science historically, much could be done to counteract this injurious effect

The experimental laboratory tends to modify the dogmatic teaching of the schools because the student there finds out for himself how exceedingly difficult it is to prove experimentally some of the simplest of the physical facts which he learned in the lecture room, and he thus gams a first-hand knowledge of the order of accuracy of physical measurements and of the difficulty in attaining it. Science taught historically would be infinitely more interesting and instructive, but time is the great In a recent leading article in the Times obstacle the teaching of the history of science was advocated as a subject for general culture, and comment was also made on similar recommendations emanating from an American writer. Such a study would introduce a better understanding of the science of invention among those who have not given particular attention to it, and the inventor might come to be regarded as a necessary and valuable cog in the wheel of industrial progress, and not, as he is too often regarded, as a freak. After all, the inventor is simply trying to make things simpler and easier and safer for his fellow-men, and he is succeeding beyond belief. Surely that object is worthy of recognition and encouragement.

A second possible remedy to encourage invention and minimise its difficulties is by means of legislation. I hesitate to enlarge on this point because the question of patents is a controversial one among scientists, and between inventors and the outside public, but it seems to me anomalous that a man who makes an epoch-making invention which is going to revolutionise an industry and add millions to the wealth of the nation, receives exactly the same degree of protection for his invention as the man who invents a new kind of shirt button. In the first case the invention will take years to develop, and may cost thousands of pounds in the process, and by the time it reaches the productive stage the patent may have expired In the case of the shirt button, a term which I use figuratively, there are no difficulties to overcome, practically no expense, no loss of time, and a clear sixteen years' trade monopoly

I know that a patent is granted only for a new method of manufacture, which has to be described in the patent specification so that any one skilled in the art may put it into practice at once simple inventions which form the subjects of the great majority of patents this is actually the case, but there are undoubtedly cases where what appears to the inventor to be a practical scheme, and was honestly described by him as such, proves afterwards to be difficult to put into effect on account of technical difficulties which he had not foreseen, and the remedy for which may not Such obstacles and their remedy be patentable cannot be recorded in the patent, because they have not been encountered when the specification Under our present system a period of nine months is allowed between filing the provisional and complete specifications, which period, while ample in the case of most inventions, is madequate for full investigation of the really great inventions, and it is to this difference between major and minor inventions that I wish to direct attention

In America it is possible for an applicant for a patent, by filing periodical amendments of his specification, to keep the application pending in the Patent Office for a number of years, during which he can be developing the invention and adding to the specification any further explanations which may be called for in the light of the experience gamed. Then when the patent is eventually issued, it runs for seventeen years from the date of issue, whereas a British patent dates from the date of application. In addition to this, an American patentee, on any question of priority of invention, is allowed to produce any evidence that may be available to show conception of the invention up to not more than two years anterior to the date of his original application. In this way an American inventor can spend several useful years perfecting his invention before his patent is granted, while the British inventor has often to watch the most useful years of his patent being eaten up in unproductive development.

I admit that the American system has drawbacks from the point of view of an industry, but it has certain undoubted advantages, and I suggest that the British system does not meet the needs of great inventions, between which and the ordinary minor inventions there ought in my opinion to be some discrimination. Merely as a suggestion, I see a possible solution in an extension of our present system of granting Patents of Addition, that is, a patent for an improvement on a prior patented invention, the Patent of Addition being granted during the lifetime of the original patent and running conterminously. If a Patent of Addition could be granted to an inventor in approved cases on production of evidence of genuine difficulties encountered and successfully overcome, these difficulties and their remedy to be fully described in the patent for the guidance of the industry, and if this Patent of Addition could be made valid for a definite term of years, one of the main fears of a patentee would be overcome.

It will be noticed that in this last suggestion I have stipulated that the specification of a Patent of Addition such as I suggest should contain

not only a description of the finished invention but also of all the difficulties encountered in its production and the steps taken to surmount them In fact, it is mainly for this reason that I make the suggestion at all I am trying to devise a means to prevent future inventors and industry from being handrcapped in a way that has been all too common in the past. I have already touched on what must be the large volume of valuable scientific information that has been lost through lack of records of past difficulties Patent specifications are m many cases the sole record of inventions, yet in the cases of the type I have mentioned they tell us nothing of the difficulties, simply because the specification is written before the difficulties are encountered. I therefore suggest that if any additional protection be given to a patentee in virtue of work done in converting his invention into a practical mechanism in face of unsuspected obstacles, the grant should be absolutely conditional on his placing on public record for the guidance of others a complete history of his efforts so that no one may have to contend with the same troubles again

I have one more suggestion to offer. On this question of assisting future inventors by increasing the store of knowledge at their disposal, I see a possible sphere of usefulness for the British Association and kindred institutions by encouraging the great inventors of to-day to place on record and publish through the medium of the Association or institution an account, even a brief one, of the main historical features of their inventions. If considerations of patents or of personal diffidence make it undesirable to publish these records at the time they are written, that need not impede the scheme, as publication could be made afterwards at a more convenient time or, say, after the inventor's death. The main thing is to have some authentic record from the inventor or discoverer himself recording the origin, growth, and development of his idea, the difficulties that beset him, and the manner in which they were overcome.

Nor do I think we should stop there. In my opinion too much attention has been paid in the past to success and too little to honest failure. It is one of our human frailties to look with something of contempt on the man who has failed to reach his goal, but this is not the attitude of the great minds, nor should it be the attitude of modern science On one occasion Lord Kelvin was shown a report by a professor on a research carried out by a research scholar, in which the professor had made some rather contemptuous remarks on the results attained because these results were mainly negative. Kelvin was highly indignant. All he looked to was the fact that the young scholar had done his best on a subject which merited investigation and in face of undoubted difficulties, and it amazed him that any scientist should speak slightingly of the results, simply because they were negative, when the real thing of value was the earnest and diligent search after truth.

If, therefore, my suggestion be adopted by the

British Association, would it not be in the best interests of science to remember the failures as well as the successes, and to encourage all serious workers in important fields of research to furnish in the common cause a record of their work, even when their aim has not been achieved, giving a faithful account of all the difficulties and all the efforts made to surmount them? Who knows but that many of the so-called failures of yesterday may only be waiting for other hands to-day to carry them on to a greater success than the world has yet known? Left to themselves they will lie in oblivion, yet, for all we know, two of them may fit together and provide the answer to one more of the riddles of the universe

Knowledge forms the working tools of science, and my proposal is in no way aimed at giving the scientific workers of to-morrow an easy task will probably have a far more difficult task than ours, but I do not think it fair to condemn them to spend part of their time in a preliminary and possibly fruitless search for tools which we have forged and hidden

As one lamp lights another, nor grows less," science of to-day will partly fail in its clear duty if it fails to pass on to to-morrow any of the knowledge which it has been privileged to acquire, or if it forgets that it is for to-morrow, rather than to-day, to assess the true value of to-day's success

and failure.

# Obituary.

Prof. W. Einthoven, For Mem RS DROF. WILLEM EINTHOVEN, whose death on Sept. 28 at the age of sixty-eight years has been announced, was one of the foremost of modern physiologists. For nearly forty-two years he has been professor of physiology at Leyden, Holland, being invited to succeed Heynsius in November 1885, and actually taking up his duties, after passing his final State examination in medicine, on Feb 24, 1886. For the first twenty years of his office the chair of physiology was combined

with that of histology.

Einthoven was born in Semarang, in the Dutch Indies, where his father was in medical practice. After his father's death, his mother with her six children settled in Utrecht, where Einthoven was educated at school and as a medical student in the University. He spoke with gratitude of his teachers there, particularly of the physicist Buys Ballot, and then of the anatomist Koster, the ophthalmologist Snellen, and the physiologist Donders. His first scientific investigation was carried out with Koster on the mechanism of the elbow joint; he assisted Snellen both in private practice and in the clinic, and in 1885 his dissertation, "Uber Stereoskopie durch Farbendifferenz," was approved by Donders for the degree of doctor of medicine.

Einthoven's investigations cover a wide range, but they are all notable for the same characteristic —the mastery of physical technique which they Einthoven, in spite of his medical training and his office, was essentially a physicist, and the extraordinary value of his contributions to physiology, and therewith indirectly to medicine, emphasises the way in which an aptitude—in Emthoven's case a genius—for physical methods can aid in the solution of physiological problems. His papers are published in the Nederlandsch Tijdschrift voor Geneeskunde, Archives Néerlandaises, Archives Internationales de Physiologie, Brain, Quarterly Journal of Experimental Physiology, Annalen der Physik, and especially in Pfluger's Archiv für die gesammte Physiologie. He wrote an article in Heymann's "Handbuch der Laryngologie und Rhinologie," and edited ten volumes of "Onderzoekingen Physiologisch Laboratorium, Leiden.'

Einthoven's name is connected chiefly with the string galvanometer and the electrocardiogram. The potential differences involved in the electrical phenomena of the heart beat are fractions of a millivolt and occur in thousandths of a second The problem of recording these small and fleeting changes, previously attempted without complete success with the capillary electrometer, was solved in 1903 by the invention of the string galvanometer, to-day there are hundreds, probably thousands, of these instruments all over the world, and they have been applied not only to their original purpose of registering the action current of the heart (and incidentally of muscles, nerves, and retina), but also to such diverse uses as finding the velocities of shells, receiving and recording wireless signals, and locating enemy guns, and I believe it is true that Einthoven never received any material profit from his invention. In 1909 he published the first complete description of the instrument, while in the last few years, employing fibres of almost ultramicroscopic size working in a high vacuum, he has succeeded, in collaboration with his son, an electrical engineer, in recording potential changes of frequencies of the order of 100,000 per second. It may be mentioned also that recently, by means of fibres of extreme thinness, he was able to register directly, and with very little distortion, sound waves of more than 10,000 vibrations per second.

Einthoven's most important work, for which he was awarded the Nobel Prize in 1924, was his discovery of the mechanism, of the manner of production, of the electrocardiogram and its characteristic waves. In many directions the diagnosis of maladies of the heart has improved in recent times, but the greatest single advance was made by Einthoven in applying the string galvanometer to the investigation of the electrical phenomena of the normal heart-beat. This work was followed up, particularly by Sir Thomas Lewis in London, and has resulted in a clearer understanding of the cause of some common disorders of the heart, and in improvement in their treatment.

Of the more personal side of Einthoven's life one might write of the grace, beauty, and simplicity of his character He spoke with ease three languages as well as his own, he was a regular attendant at international gatherings, he threw all his influence on the side of good international Last summer he was present relations in science at the International Congress of Physiology at Stockholm, and attended the various functions, and took part in many of the excursions, including a trip to the north of Sweden and back by sea along the Norwegian coast. It was a wonderful thing to be his guest and to enjoy the delightful hospitality of his home. He invited me some years ago, while we were attending a German congress of physiologists at Tübingen, to stav with him at Leyden on my way back to England We arranged to meet at a station m North Germany and to travel the last part of the journey together I waited until his train arrived. He came literally running along the platform to meet me, seized my bag out of my hand, carried it to the carriage, where he had kept me the best seat, and made me feel that whatever the difference of our age and position, I was from that moment his honoured guest. In 1924 we sailed together to America, and at night under the starlit sky we walked on the upper deck discussing the random movements of electrons in conducting fibres and other matters equally strange. These personal details will emphasise what a loss his passing will be, not only to his older colleagues and to his younger friends, but also to all the good fellowship of physiologists throughout the world.

Einthoven was elected an honorary member of the Physiological Society in 1924, and in return he invited the Society to hold one of its meetings in his laboratory. The occasion will be a happy memory in the minds of those who were able to go to Leyden in April 1925. In 1924 he visited the United States to deliver a course of lectures at Boston, and while there, the award to him of the Nobel Prize for medicine for 1924 was announced. He was elected a foreign member of the Royal Society in 1926. A. V. H.

Prof. Svante Arrhenius, For. Mem. R.S.

THE annals of physical science bear abundant testimony to the native genius and energy of Sweden, and in this respect Svante August Arrhenius, who has just passed away, upheld with honour and distinction the reputation of his country. Born near Upsala in 1859, as the son of a land steward, Arrhenius obtained his early education in the school and university of that town, moving later to the University of Stockholm, the atmosphere of which was more congenial and stimulating to the young physicist His researches there on electrical conductivity and its relation to chemical activity, although lightly esteemed by the Upsala professors, brought him recognition abroad, whilst the theory of electrolytic dissociation, put forward in 1887 during his Wanderjahre, secured for him an established position in international science.

During these Wanderjahre, with financial support provided by the Swedish Academy of Sciences, Arrhenius visited quite a number of active research centres Thus he worked with Ostwald at Riga, and later at Leipzig (the laboratory which van 't Hoff in 1888 termed the 'Hauptagentur fur Ionenspaltung'), with Boltzmann at Graz, with Kohlrausch at Wurzburg, and with van 't Hoff at Amsterdam

Refusing an invitation to settle at Giessen, Arrhenius returned to Sweden in 1891, and acted first as lecturer and afterwards as professor in the newly established Technical High School at Stockholm Somewhat later he acted as Rector of the same institution for a number of years. Glessen was not the only foreign university which made an effort to secure Arrhenius, for in 1905 he was invited to Berlin This honour was likewise declined, and in the same year he was appointed Director of the Nobel Institute at Stockholm. Arrhenius occupied this position up to the time of his death, and the numerous communications published by the Institute bear witness to the activity of this centre of research under his inspiring leadership.

Arrhenius was a frequent visitor to England, and although his scientific views met with a critical reception in various quarters, his genual and attractive personality made him always a welcome guest. His work secured extensive recognition from British scientific bodies, and he was a foreign member or honorary fellow of the Royal Society, the Chemical Society, the Physical Society, and the Royal Institution Honorary degrees were conferred on Arrhenius by the Universities of Oxford, Cambridge, Birmingham, and Edinburgh, whilst the Royal Society awarded him the Davy Medal in 1902, and by invitation of the Chemical Society he delivered the Faraday Lecture in 1914

In Europe and America also his international standing was marked by his election as corresponding member of numerous academies and learned societies, whilst honorary degrees were conferred on him by the Universities of Heidelberg, Groningen, Oslo, and Leipzig Further, he was the recipient of the Nobel Prize for chemistry

The honoured place which Arrhenius occupied m physical science was without doubt mainly due to his bold and original ideas on the condition of dissolved electrolytes, as expressed in his theory of electrolytic dissociation, and it is on this ground that he is justly regarded as one of the founders of modern physical chemistry. The genesis of this theory in Arrhenius's mind, on the basis of his own experimental work and in correlation with van 't Hoff's researches on osmotic pressure, is worth recalling, for it constitutes one of the most interesting chapters in the history of physical chemistry.

Investigation of the electrical conductivity of forty to fifty substances in dilute aqueous solution had led Arrhenius in 1883 to two striking conclusions: (1) that in regard to conduction of the electric current only part of the electrolyte is to be regarded as 'active,' this proportion increasing on dilution, and (2) that there is a parallelism between the 'strength' of an acid and its electrical conductivity. The conception of the 'activity coefficient' as a 'degree of ionisation' came later, and was not published until Arrhenius had become acquainted with van 't Hoff's memoir on the extension of the gas laws to solutions. The abnormal behaviour of dissolved salts, expressed by the van 't Hoff factor i in the equation pv = iRTwas precisely the point on which Arrhenius fastened as of special significance for his theory of dissociation. He writes from Wurzburg to van 't Hoff under date March 30, 1887. "Die Abhandlung [i e van 't Hoff's memoir] hat mir namlich in unerhortem Grade Klarheit geschafft uber die Konstitution der Losungen," and he proceeds to the correlation of osmotic abnormality and This correlation was the main feature of the communications made by Arrhenius in 1887 to the Swedish Academy, and of the classical paper "Uber die Dissociation der in Wasser gelosten Stoffe," published in the Zeitschrift fur physikalische Chemie. An early announcement of these new developments was made also to Sir Oliver Lodge as secretary of the British Association Committee on Electrolysis.

It was fortunate for the propagation of Arrhenius's ideas that he was in alliance with van 't Hoft, and that he had such an able and enthusiastic advocate as Ostwald. The newly established Zertschrift fur physikalische Chemic, run mainly by Ostwald, provided an effective platform for the discussion of the new theory and the relevant experimental investigations. Arrhenius's views evoked strong opposition in many quarters, but as the years passed the utility of this theory as a basis for the study of solutions on quantitative lines became more and more apparent. The theory stimulated a prodigious amount of research, and if modifications have been made and are still being made, the ideas of Arrhenius have nevertheless yielded an abundant harvest.

In the experimental investigation of problems suggested by the new views on solution Arrhenius himself, as well as his co-workers in the Nobel Institute, took a prominent part. Such matters as the diffusion of electrolytes, neutral salt action, the hydrolysis of salts, the catalytic activity of acids, isohydric solutions, were examined from the viewpoint of electrolytic dissociation, and the extent determined to which the new theory was capable of giving a quantitative account of each case.

The study of physiological and biological problems on quantitative physico-chemical lines was another field in which Arrhenius was active, both theoretically and experimentally. He concerned himself more especially with serum therapy, and many of his original papers and books deal with aspects of this subject, such as the relation of toxins and anti-toxins.

From serum therapy to cosmogony seems a long step, but the latter also was a subject in which Arrhenius was deeply interested, and the varied problems of which occupied much of his thoughts.

The nature of planetary atmospheres, the genesis of the solar system, the origin of the aurora, the influence of carbon dioxide on the temperature of the earth, the function of light pressure, and the periodicity of certain natural phenomena were among the problems on which Arrhenius expressed fresh and original views

The contributions of Arrhenius to serum therapy and to cosmogony were both striking and important, but without doubt the honourable and permanent place which his name occupies in the roll of men of science is due, not to his work in these two fields, but to the fresh impetus given by him to the study of solutions on quantitative lines JCP.

THE RIGHT HON THE EARL OF IVEAGH, FRS

THE Earl of Iveagh, who died on Oct 7 in his eightieth year, distributed large sums for public objects. Consideration for the sufferings of others was one of his noblest characteristics, and his contributions to hospitals in Dublin and elsewhere were on a princely scale When the Boer War broke out, he equipped the Irish Field Hospital, and during the Great War he spent vast sums in increasing the provision for our sick and wounded Lord Iveagh was, however, a philanthropist embued with a spirit of social reform The urgent appeal of sickness and suffering is responded to by many according to their means, but other of Lord Iveagh's repeated acts of benevolence indicate a considered scheme to increase the well-being by improving the health of the people

In 1889, Lord Iveagh gave £250,000 for the substitution of sanitary dwellings for slums in Dublin and London. Nine years later he provided a similar sum to improve a congested and noisome area abutting on St. Patrick's Cathedral, Dublin By this scheme the old dwellings and streets were done away with and a public garden of about two acres was provided around the Cathedral. Upon the rest of the seven and a half acres model dwellings for working people were erected, with a central play-hall for the children.

Prior to 1907 the congested state of the old markets in Dublin and the surrounding areas was not only an eyesore but also a serious menace to the public health. At this date Lord Iveagh bought up the whole area, built modern markets, and presented this valuable property to the city. He was, indeed, a practical hygienist, for there is no better means of improving the health of an urban population than providing it with good housing and opportunities to spend more time in the open air and sunlight. One of the latest of Lord Iveagh's benefactions was destined to increase the facilities for recreation in the open air of the citizens of London. In 1925 he purchased the residue of the Ken Wood property adjoining Hampstead Heath, which the Preservation Committee had been unable to acquire owing to exhaustion of its resources. The whole of this fine place of woodland now becomes public property.

The idea of furthering the public health by stimu-

lating medical discovery seems to have originated in 1896 owing to an accident to one of Lord Iveagh's employees. A labourer upon his estate having been bitten by a rabid dog, he directed that everything possible was to be done for the unfortunate man, but was surprised to learn that the treatment for hydrophobia could only be secured by sending the patient to Paris This was done, and no further ill results ensued, but the novelty of the treatment and the absence of facilities in England for the prosecution of researches such as had led to Pasteur's fruitful discovery made a deep impression on his mind. In 1898, Lord Iveagh visited the Pasteur Institute, and the project of endowing a sımılar ınstitute in London began to take shape Ascertaining that the Lister Institute (then the Jenner Institute) had been founded with the objects he had in view but was languishing for want of funds, he decided, after careful inquiry, to endow the Institute to the extent of £250,000, subject to certain alterations in its constitution and government.

Another institute for medical research, as well as the treatment of patients, which is largely indebted to Lord Iveagh's liberality, is the Radium Institute in Riding House Street, London. This was founded in 1909 to make researches upon the effect of radium on the human organism and to supply treatment to patients whose circumstances did not permit them to receive the benefit of radium treatment without financial help. The whole of the money required for the building, equipment, and endowment of the Radium institute was provided by Lord Iveagh and the late Sir Ernest Cassel

Lord Iveagh made large benefactions for various purposes to his old college, Trinity College, Dublin, and built for it new Institutes for physics and botany, and endowed the school of geology new National University of Ireland also is indebted to him for a valuable site at St. Stephen's Green.

Even a complete list of Lord Iveagh's known gifts for public purposes would fail to record many of the benefits he dispensed. Partly from a distaste | five years of age.

for notoriety, partly for self-protection, the hand of the donor was concealed His philanthropic enterprises were carefully considered and evolved with patience and attention to details. He took a personal interest in all his schemes and often a large part in the direction of them

In 1906, Lord Iveagh was elected a Fellow of the Royal Society under Statute 12 "as having rendered conspicuous service to the cause of science," and in 1908 he was unanimously elected chancellor

of the University of Dublin

We regret to announce the following deaths:

Dr. Charles C Godfrey, president of the American Association of Variable Star Observers, conducted in co-operation with the Harvard Observatory, on Aug. 31, aged seventy-one years.

Dr. B. Daydon Jackson, secretary of the Linnean Society of London for forty-seven years, editor of the "Index Kewensis," and author of other important botanical works, on Oct. 12, in his eighty-second year

Dr. William Libbey, professor of physical geography and Director of the Museum of Geology, Princeton University, from 1883 until 1923, on Sept. 6, aged

seventy-two years.

Prof. Alexander Mair, professor of philosophy in the University of Liverpool, president in 1925 of the Association of University Teachers, and author of "Philosophy and Reality" (1911), on Oct. 8, aged

fifty-seven yours. Dr. J. W. Mollison, C.S.I., formerly Inspector-General of Agriculture in India, who was the first head of the Imperial Agricultural Research Institute at

Pusa, on Oct. 4, aged seventy years.

Dr. Eugene Allen Smith, emeritus professor of mineralogy and geology in the University of Alabama and state geologist since 1873, who was vice-president (Section E) of the American Association for the Advancement of Science in 1904, on Sept. 7, aged

eighty-five years.

Mr. H. M. Taylor, F.R.S., semor fellow and formerly mathematical lecturer of Trunty College, Cambridge, distinguished by his contributions to mathematical science and his translation of many scientific works into Braille for use by the blind, on Oct. 16, at eighty-

# News and Views.

THE amount of change a story can undergo through repeated copying is a commonplace of experimental psychology; and every scientific worker in the habit of verifying original references has met with examples where the actual statements of an early investigator differ substantially from the versions of them to be found in more recent writings. But it is not often that one meets so extreme a case as that given by Mr. Gheury de Bray m a letter to NATURE of Sept. 17, and in an article in the present issue. Of eleven determinations of the velocity of light quoted in standard works, only one turned out to have been quoted correctly. Mr. de Bray's historical work should provide material for any one in need of examples for the precept 'Verify your references.'

In a paper in the Astronomische Nachrichten (No. 5520), Mr. de Bray has used what appear to be the best of the determinations, after due criticism, and has shown that they point to a decrease in the velocity of light of about 200 km./sec, in the last fifty years. As he says, however, the earlier determinations are not good enough individually to determine such a change, and his argument rests on the fact that they all agree in suggesting a change in the same direction. Of the seven determinations retained, one differs from 299,800 km./sec. by 2.2 times its probable error, one by 20 times, and the rest by smaller multiples. In a random set of observations 1 in 5 would deviate from the true value by more than twice the probable error. The velocity of light being so fundamental a constant, physicists may prefer to attribute any change in its measure, if established, to a change in the unit of velocity and not to one in the velocity of light itself. The variation of the second is shown by E W. Brown's recent work to be within a few parts in 107. The possibility of measurement of wave-lengths within a few thousandths of an

Ångstrom unit indicates that the unit of length is equally constant. We can, therefore, scarcely admit such a change in the unit of velocity as would be needed to account for a change in the measured velocity of light of the order of one in a thousand. An absolute change in the velocity of light, on the other hand, could scarcely obtain acceptance unless supported by much more decisive observational material.

An international conference on the Protection of Migratory Wild Fowl was opened, under the presidency of Lord Ullswater, at the Foreign Office on Oct. 12 The conference is the successor of two preliminary meetings, held in 1924 in Sweden and in 1926 in Copenhagen, at which the need of action for the protection of wild ducks, geese, swans, and similar migrants was strongly urged by the representatives of northern European countries. The Governments of the countries concerned were favourably disposed towards the views expressed at the earlier meetings and the invitation of the British Government was accepted by the following Governments, which are officially represented: Germany, Belgium, Holland, Denmark, Sweden, and Finland, as well as Great Britain, with Dr. P. R Lowe and Mr. H S Gladstone as delegates. The discussions of the early sessions of the conference centred round the altered status of migratory wild fowl in recent years Delegate after delegate reported that migratory wild fowl were on the decrease, and this view so impressed the conference that it passed a resolution stating that in its opinion there had been a general diminution in the number of migratory wild towl, and that "in the interests of agriculture, seience, sport, the maintenance of the food supply, and the desirability of retaining natural species of beauty and interest, it is imperative that steps should be taken to arrest such diminution." Various suggestions were made as to means best suited for reaching this end, the extension of the close season, the prohibition of the slaughter of migratory wild fowl on the northward migration to the breeding grounds in spring, the prohibition of mechanically-propelled boats, of clap nets, standing nets, sunk nets, and so on; and the conference blessed them all, and added a resolution recommending the most effective protective instrument of all, that the sale of migratory wild fowl should be forbidden during the close season except under rigid conditions. It will be interesting to see what international legislative action follows upon the unanimous recommendations of the ornithologists.

At the recent International Optical Congress held at Oxford, considerable discussion was devoted to the question of the importance of good vision for all persons licensed as motor drivers. In this matter, keepness of visual acuity is not the only or even the prime consideration, since, when outdoors, one is looking at relatively large objects. The really important things are limitations in the extent of the visual fields, and the further question of binocular vision and latent imbalance of the muscles controlling the eye movements. Limitations in the visual fields do provide a dangerous disability for the driver of any

fast moving vehicle, since whilst his attention is directed straight ahead, he should still be capable and keen to detect the slightest movement (even if associated with some vagueness of form) of any other moving person or vehicle issuing from side streets or lanes into his main sphere of attention, that is, into his central field of vision. With regard to faults in the co-ordinated balance of the two eveswhich would interfere with binocular vision—it is well known that perception of depth and judgment of distance are both almost entirely attained by perfect stereoscopic or binocular vision Any person, therefore, who is deprived of this faculty, is hable to misjudge distances, and there is no doubt many accidents are caused by drivers suffering from such a visual deficiency which led him to believe that he might just clear some imminent obstacle, when in reality the actual distance away from that obstacle was much less than it appeared to be. Such defects are much more dangerous to the rest of the public than the commoner visual defects of long-sightedness or even low degrees of myopia.

ANOTHER question of public interest to which considerable attention was given at the recent International Optical Congress was that of visual efficiency in industry. This is undoubtedly a problem of some complexity, since in British industrial circles there is still some prejudice against the worker wearing spectacles In a great many workshops there is yet the old slubboleth prevailing that the wearing of glasses is a sign of the oncoming of old age, and definitely marks another prospective victim for the human scrap-heap. There is no reason why such a prejudice should still prevail, since it is obvious that the worker will produce better and finer work-with greater accuracy, fewer flaws, and less wastage, if steps are taken to ensure that he is visually efficient was reported that in some large manufactories, schemes had already been brought into operation whereby the eyes of all the workers were examined and any defect was corrected. Statistics prove that in all cases such provision had resulted in a large increase of efficiency in production and increased good health and pleasure on the part of the operative.

A FURTHER point of importance which is regularly overlooked in various trades lies in the fact that many operations are carried out at an abnormally short working distance, and in such cases—even if the operative's sight is perfect for ordinary purposesthere should be some assistance provided in the form of spectacles in order to prevent undue fatigue, headache, and the possible cultivation of more permanent defects. Such a condition of affairs is well illustrated in the process known as 'linking' in the hosiery trade, which was the subject of a special pamphlet recently issued by the government Department of Scientific and Industrial Research. Compared with the United States, there is comparatively little attention devoted to this subject by British employers. The fact that it has been proved by individual firms in such trades as printing, and in such industries as the textile in many of its branches, that both financial advantage and increase of output is a consequence of giving attention to the vision of the worker, it is to be hoped that more general attention will be paid to the question in the immediate future.

WE have already referred to the movement to establish in the Central Reference Library of Southwark a Faraday Memorial Collection, consisting of the biographies, portraits, and published works of Faraday, and the best and latest books on the sciences and their applications, particularly electricity, with which Faraday's name is so closely identified. The Mayor of Southwark mystes contributions to the Faraday Memorial Fund being raised for this purpose The annual meome will be expended year by year under the direction of a special Committee exclusively for the object in view. The use of the Faraday Memorial Collection will not be limited to local residents but, like the benefits of Faraday's discoveries, will be available for all who desire to consult it The memorial is to be mauginated by Sir Oliver Lodge on Oct 28. It is hoped that generous support will be forthcoming to the fund being raised Contributions should be sent to the Mayor, Southwark Town Hall, Walworth Road, London S E. 17. Contributors to the memorial, without regard to the amount subscribed, will be enrolled as foundation

A COMMITTEE to inquire into the organisation, development, and recruitment of the Colonial Vetermary Services has been appointed by the Secretary of State for the Colonies. The committee is asked to frame proposals for obtaining the highest degree of efficiency in regard to vetermary research and administration in the non-self-governing Dependencies that financial considerations permit. The questions to be considered will embrace the recruitment and training of veterinary officers, their conditions of service, the organisation of research and intelligence, the setting up and support of any institutions required, and methods by which the financial expenditure involved can best be met. In framing its recommendations the committee has to bear in mind that the principle of the ultimate creation of a Colonial Scientific and Research Service has been approved by the Colonial Office Conference, and that specific proposals for the formation of an Agricultural Scientific and Research Service for the non-selfgoverning Dependencies, with which the veterinary service must necessarily maintain close liaison, are now being framed. The committee consists of . Lord Lovat (Chairman), the Right Hon. W. Ormsby-Gore, Sir Arnold Theiler, Prof. J. B Buxton, Prof. R T. Leiper, Dr. W. H. Andrews, Dr. J B. Orr, Mr. W. C. Bottomley, and Major R. D. Furse, with the addition of an officer with experience in the Colonial Service. Major G. S. M. Hutchinson, Colonial Office, is secretary to the committee.

In Great Britam, while there are evident the most divergent attitudes towards the problem of birth control, there is no organised attempt to make discussion or propaganda illegal. It is not widely known that in other countries such attempts are being made,

and that in certain countries they have been successful. It may, therefore, be of some interest to give a brief résumé of the position stated in a detailed communication received from Dr. Maile Stopes. The American Coinstock Law was originally designed to prevent the sending by post of indecent pictorial postcards and similar matter. During its progress into law obscene matter was defined so as to include any directions, drugs, or articles for the prevention of conception, and it is now an offence punishable by a 5000 dollar fine, or five years imprisonment or both, to send birth control information by post. The French Law of 1920 is more comprehensive. It punishes by one to six months' imprisonment, and a fine of from 100 to 5000 francs, any one who explains or offers to explain birth control methods, or devotes himself to contraceptive propaganda, or propaganda against childbirth. Similar steps have been taken in other countries The present position, however, is not easy to ascertain, because the measures often assume the form of extending by administrative order the definition of obscene publications, with the result that in certain countries, Belgium and Canada, for example, publications having reference to contraception are seized by post office or custom house officials, or both. A Committee appointed by the Minister of Justice of the Irish Free State recently reported in favour of an amendment of the Indecent Advertisements Act so as to make illegal the sale of literature concerning contraception.

ATTENTION was directed in Nature of July 9 last to the popularly written leaflets on astronomical matters issued by the Astronomical Society of the Pacific. Two further leaflets belonging to the series have now come to hand, bearing the titles "Explormg the Depths of Space" and "The Pons-Winnecke Comet," and others are in course of preparation. In addition, the Society (the address of which is 803 Merchants Exchange Building, San Francisco, Califorma) has, for the last two or three years, arranged series of illustrated popular lectures in San Francisco on various aspects of astronomical research and discovery, delivered by astronomers of repute, to which the public are admitted free of charge. Leaflets contaming syllabuses of the lectures have been issued, at the backs of which are collected useful astronomical data and, in some instances, diagrams of the night sky at various times during the year. During the present session, for example, a series of four lectures will be given by Dr. Wm. F. Meyer, assistant professor of astronomy in the University of California, on the general subject, "From Atom to Island Universe," the titles of the individual lectures being "The Atomic World," "The Interior of a Star," "Island Universes," and "The Night Sky of Winter." An annual visit to the Lick Observatory is conducted by the Society, in connexion with which pamphlets are issued containing information relating to the most interesting objects visible at the time. We hope that a large measure of success will attend these praiseworthy efforts for the popularisation of astronomical knowledge. It is perhaps not generally understood that membership of the Society, including the receipt

of all publications and privileges, is open to all, irrespective of nationality or astronomical qualifications.

The Council of the Iron and Steel Institute has awarded the Carnegie Gold Medal for the year 1925 to Mr A. L Curtis, Westmoor Laboratory, Chatteris, in recognition of his research work on steel moulding sand, etc.

THE Thomas Hawksley lecture of the Institution of Mechanical Engineers, on "Application of X-rays to the Study of the Crystalline Structure of Materials," will be delivered by Sir William Bragg, on Friday, Nov. 4, at 6 o'clock P.M

SIR WILLIAM LARKE, Director of the National Federation of Iron and Steel Manufacturers, has been appointed by Order of Council dated Oct 5, 1927, to be a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

Mr. F. J. Blight, who since 1894 has been associated with the well-known firm of scientific and technical publishers, Messrs Charles Griffin and Co., Ltd., and has been head of that house since 1899, is retiring from that position. Many authors of scientific and technical works published by Messrs Griffin appreciate the valuable services rendered by Mr. Blight to the production of specialised works on important aspects of modern science and industry, and trust that there are still before him turther years of useful life and influence even in his retirement.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in building trades and a lecturer in turniture trades in the Technical College, East London, South Africa-The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (Oct 31). A research chemist for work on plasters and other materials used for impressions and models in dentistry—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W I (Nov. 7). An engineer for the Sanitary Department, Buildings and Roads Branch, Government of the Punjab—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, SW1 (Nov. 10) A demonstrator in physiology at St. Bartholomew's Medical College-The Dean, Medical College, St. Bartholomew's Hospital, E.C.1 (Nov. 16) A chief lecturer in chemistry at the Woolwich Polytechnic-The Principal, Woolwich Polytechnic, SE 18. A naval architect for the Marine department of the Government of Nigeria-The Crown Agents for the Colonies, 4 Millbank, S.W 1 (quoting M/6) A junior technical officer in an Admiralty experimental establishment, mainly for experiment and design in connexion with wireless and other electrical apparatus — The Secretary of the Admiralty (CE. Branch), Whitehall, S.W.1 principal of the Massey Agricultural College, New Zealand—The High Commissioner for New Zealand, 415 Strand, W.C.2.

### Our Astronomical Column.

Magnetic 'Storm' and Sunspots —On Oct 12, at  $10\frac{1}{2}^h$ , a considerable magnetic disturbance commenced and lasted until  $2^h$  on the following morning. The chief characteristics as shown by the declination magnetograph records at Greenwich were, first, the sudden commencement; and secondly, the occurrence between  $18^h$  and  $21^h$  of three distinct waves of magnitude about 30', 25', and 40' respectively. The total range in declination throughout the disturbance was about  $1^\circ$ . A lesser disturbance, of interest on account of its sharp commencement, also took place between Oct 9,  $20\frac{1}{2}^h$  and Oct 10,  $23^h$ 

At the time of the phenomena there were three groups of sunspots within a short distance of the sun's central meridian, as follows.

	Central Mendian Passage	Latitude.	Area on Oct. 9	
l.	Oct. 9.4	19° N	300, Millionths of	:
$^2$ .	Oct 10 6	12 S	500 sun's hemi-	
3.	Oct. 116	19 S	250) sphere.	

Both (2) and (3) were returns of large groups, conspicuous in the previous rotation, to which attention was directed in Nature of Sept. 24, p. 456. A large area of bright faculæ surrounded these two groups of which (2) showed marked changes after Oct 7, when new spots appeared. A connexion may reasonably be attributed between this group of spots and the magnetic 'storm' of Oct. 12.

METEOR SHOWER OF (HACOBINI'S COMET.—Mr. W. F. Denning writes that "two observers watched the sky from Bristol on Oct 8, 9, and 10 from about 6.30 p.m. to 9.30 p.m., though the moon was near the full and some fog prevailed. The object was to

observe a few meteors from Gacobini's comet, the orbit of which hes near the earth's path on Oct. 9-10. It may be remembered that last year a definite shower was witnessed on Oct. 9 with a radiant agreeing with that computed for the comet named. Owing to the unfavourable conditions, tew meteors were noticed this year, but on Oct. 8 about eight were seen and ten on Oct. 9. A fine flashing meteor was seen on Oct. 8 at 7.56 PM. in the south-west, but it could have had no association with Giacobini's comet. On Oct. 9 seven meteors were recorded, which showed diffuse radiation from 260° + 53°, and there is little doubt that this shower represented a return of the display of 1926, as the date agrees and the position of radiation, in the head of Draco, nearly coincides. No doubt the display would have been more abundant and the individual objects more brilliant but for the fog and moonlight which made the circumstances extremely unfavourable."

Photometry of the Moon's Surface.—Astr. Nach. No 5524 contains observations of the albedo of various regions of the moon, made by A. Markov at Pulkovo. The observations were photographic on Agta plates. Photographs of stars and of a standard lamp were taken for comparison. Aristarchus is the region of highest albedo, the value being 0 37, Tycho and Proclus coming next. It will be noticed that the value is far below that for snow, which some had suggested as possibly present on the brighter regions. The darkest regions are Schickard and Grimaldi with values 0 09 and 0.07. The mean albedo of the disc is about 0.16, in good agreement with former determinations.

## Research Items.

CAVE EXPLORATION AT LESPUGUE, FRANCE.-Cultural and chronological relations of some importance have been established by excavations in the Grotte de Gouerris at Lespugue, which have been carried out by M. le Comte de Saint Périer, and are described by him in L'Anthropologie, T. 37, Nos. 3-4. The cave was first discovered by Miss D. Garrod. When excavated it was found to contain three levels of occupation. Of these the latest was neolithic, when the cave was not used as a dwelling-place but solely for purposes of burnal. Traces of fire have been discovered, which probably points to the preparation of funeral feasts in the cave. No signs of the habitation-sites of the people using the cave for burial purposes have been found in the neighbourhood. Of the two preceding occupation levels, the earliest was that of a palæolithic people, who, it is suggested, made no prolonged stay. Probably they were hunters following the herds of reindeer of which the remains are abundant. They belonged to an early stage of the Magdalenian epoch when the harpoon was still unknown. They appear to have been related to the population of Perigord rather than that of the Pyrenees. After a period which allowed of a considerable deposit of stalagmite, they were followed by a people of low culture. The climate by then had become warmer and more moist. This people, as is indicated by their culture, belonged to the very beginning of the transition period. There are many Magdaleman types of implement. The harpoons are not of the typical Magdaleman style, yet they have not yet attained the Azilian form with teeth on both edges. A comparison with Mas d'Azil establishes the position of this culture as between the latest Magdalenian stratum at Mas d'Azil (Couche D of Piette) and the stratum E in which the coloured pebbles and the full-fledged Azılıan culture were found. Thus Piette's contention that the large flat harpoon with unilateral barbs belonged to quite the beginning of the transition period is not only supported but also is given greater precision in date.

CRIMINAL STATISTICS.—Statistics relating to criminal proceedings, police, coroners, prisons, and criminal lunatics for the year 1925, have recently been published (London: H.M. Stationery Office. 4s. net). Not only are the actual figures given for the period surveyed, but also comparative tables and graphs, so that the 'peak' periods and the variations at different periods can be studied. Allowance has of course to be made for the increase in population by about seven millions since 1899: it is suggested that the safer figure for comparative purposes is the proportion the indictable offences known to the police have borne to every 100,000 of the estimated population. crime rate would seem to have fallen since 1857: for the period since 1899 the worst year is 1908. Here would appear to be reflected the effect of the Boer War. Six years after this war the increase in indictable offences was checked, and it is hoped that the similar increase since the War of 1914-18 will also be arrested. While there has been a tendency for the number of homicides to decrease in number, crimes against property, i.e. burglary, etc., have increased during the period 1899–1925. The volume will be of very great service to all those interested in social conditions, as well as to those officially concerned with the problems involved.

QUANTITATIVE METHODS IN GEOGRAPHY.—In an attempt to test and compare the intelligence of communities, Prof. E. Huntington has utilised the census figures showing the number of persons of

various ages in the American States. Arguing that these figures should show a steady decrease from one upwards and so be represented, when plotted, by a smooth curve, he shows that the curves are extremely irregular in many of the States where negroes are numerous. This he maintains is due to carelessness or ignorance The age of the children is forgotten or merely stated in a round figure in order to save trouble. Soveral of these curves are produced in an article in the Scientific Monthly for October entitled "The Quantitative Phases of Human Geography." Prof Huntington has also compiled a map of the United States showing accuracy of census returns as to age based only on native whites of native parentage in order to eliminate, so far as possible, questions of race. This map shows the highest degree of accuracy in the northern States, with a steady falling off towards the south and especially the south-east, except for Florida, where recent migration from northern States has been marked In Nevada the standard is low, probably due to the decay of the mining industry and the drifting away of the more intelligent classes. The paper also contains other maps compiled from census statistics.

LIMNOLOGY IN CALIFORNIA.—The region in which Stanford University lies, the Santa Clara Valley, California, owing to its brief rainy season, is dependent throughout the summer on irrigation. university supply is from a small artificial reservoir I mile long and I mile wide, the Scarsville Lake. Dr. Flora M. Scott has recently carried out a proliminary survey of this lake ("Introduction to the Limnology of Searsville Lake," Stanford University Publications, University Series, Biol. Sci., vol. 5, No 1, 1927, pp. 1-83). According to Whipple's classification, this is a 'tropical' lake, the surface temperature never falling below 4° C. The greatest depth does not exceed 7 m., and circulation is therefore ensured. The plankton content is, however, temperate in character and shows a seasonal rotation of sub-arctic to sub-tropical forms in the course of the year. The Bacillaries as a group culminate in the spring, the Chlorophycee and Cyanophycee give rise to the summer maximum, while flagellates persist throughout the entire season. In the summer of 1924 the level of the lake became so low that the fish died off, and for hygienic reasons the lake had to be drained. Opportunity was then taken of carrying out some culture experiments with the dry surface mud from the lake bottom. If the solutions were kept acid (pH 5) no plankton organisms could be cultured from the mud samples, but under alkaline conditions the plankton soon became abundant. When the cultures were maintained at a temperature of approximately 34°C., the blue-green alga Oscillatoria alone succeeded in thriving.

Fresh Water Biology in Norway. In 1905 the Academy of Science in Oslo received, by will, an estate from Herrn Direktor F. O. Guldberg on condition that a biological research station was set up. The first ann was by means of farming to secure a fund; and in 1925 sufficient had accumulated to buy a property on the Hurdals-See for which a boat-house, motor-boat, etc., were provided. In a recent report Prof. H. H. Gran and Miss Birgithe Ruud give some preliminary results ("Über die Planktonproduktion im Hurdals-See," Vidensk Acad. Oslo I. Mat-Naturvid. Klasse, 1927, No 1, pp 1-33). The Hurdals-See is a lake of average depth and of the type with stagnation in the bottom water in summer

and winter, and vertical circulation to the bottom in spring (May) and autumn (November) The discontimuity layer lies in summer between 10 m. and 25 m. Lowering leaves of Ranunculus aquatilis peltatus in bottles to different depths, and noting the oxygen exchange, showed that the point at which assimilation equalled respiration lay between 6 m and 8 m. For diatoms and brown flagellates this depth was greater. Quantitative investigations of the centrifuge plankton showed that whereas the flagellate Dinobryon sertularia had a summer maximum in June, all other species increased slowly throughout summer, reaching a maximum in September. The chief forms were Tabellaria fenestrata, Cyclotella comta, Melosira distans, and Staurastrum jaculiferum. As regards quantity of phytoplankton, the Hurdals-See does not differ essentially from most lakes in central Norway according to Naumann's designation, an 'oligotroph'

AMPHIOXUS.—Dr. V Franz of Jena has given in "Die Tierwelt der Nord- und Ostsee" (Leipzig: Akademische Verlagsgesellschatt, 1927, Lieferung 8, Teil XII b, "Branchiostoma") an account of Amphioxus which is a beautiful little monograph in itself Branchiostoma lanceolatum, as Amphioxus is now called, is the only European representative of the class Acrania, which altogether includes about a dozen species. This is, however, the only really well-known form which both on account of its primitive vertebrate character and its comparative accessibility is beloved of all zoologists, and an enormous amount of literature has been amassed dealing with this single animal. From the collection Dr Franz has sitted out the interesting and important, and made a most useful summary, anatomical, embryological, and physiological. He is well equipped for undertaking such a work, as he has himself made considerable contributions during the last few years to the minute anatomy and behaviour of Amphioxus, including studies of the methods of movement, reactions to light and researches on the sense organs and sense cells.

THE LUNG-WORM AND THE STOMACH-WORM OF THE Cat.—Dr. T. W M. Cameron (Jour. of Helminthology, June 1927) has investigated the life history of the lung-worm and of the stomach-worm of the cat The former, Elurostrongylus abstrusus, lays its eggs in the alveoli and in the pareschymatous tissue of the lungs and there the larvæ hatch, pass up the trachea, are swallowed and pass out with the fæces. A description is given of the morphology and biology of the larva. When infected faces are eaten by mice the larvæ migrate from the stomach of the mouse to the muscles and subcutaneous tissue where they encyst, and within three weeks develop into the infective stage, which may remain viable in the muscles for at least a year. If an infected mouse is eaten by a cat the larvæ escape from their cysts, reach the lungs, and within six weeks become mature adults. stomach worm, Ollulanus tricuspis, lives on the surface of the gastric mucosa and in the acini of the The first-stage larva emerges from the egg in the uterus of the worm and moults there. second-stage larva develops into the third-stage larva which is found outside the parent worm, but the exact period at which it left the parent was not determined. This larva leaves the stomach of the cat in the vomit (and possibly in other ways, though no other has been discovered) and is swallowed by a new host in which it develops into the fourth-stage larva and finally into the adult. The characters of these four larval stages are described and figured. Hitherto it has generally been accepted that Ollulanus tricuspis had a complex life history requiring an intermediate host—the mouse. This view arose through the confusion of the larvæ of Ollulanus and Elurostrongylus Leuckart found larvæ in the cat and the mouse which he believed to be those of Ollulanus, but they were really larvæ of Elurostrongylus.

THE BORING UNIONID OF ASSAM.—The distribution and habits of the remarkable boring unionid, at first referred in 1836 to the genus Anodonta, but now known as Balwantia soleniformis (Benson), have lately received the attention of Dr Sunder Lal Hora (Jour. Proc Asiatic Soc Bengal, vol. 21) retiring habits it has been greatly overlooked, but Dr Lal Hora is confident that it will prove widely distributed in South Cachar and several other places in the Surma valley. The animal lives in inclined burrows excavated in hard blue clay or in finable sandstone, after the manner of marine boing molluscs. The burrow is of uniform calibre throughout and its cross section corresponds with that of the shell, but is a little larger, while its length is about two inches The bivalve is anchored to the far end of the burrow by its foot, by the expansion and contraction of which it can move to and fro in the burrow, and thus by the aid of the coarse ridges on the shell enlarge its tenement at will There is no proof that the young animal starts a burrow de novo. it probably takes possession of some pre-existing hole or crack and enlarges it as required. The molluse is considered a great delicacy by the Uriya coolles, who have an ingenious way, that is fully described, of extracting it from its crypt

Afforestation in Michigan —Those interested in the afforestation work proceeding in Britain should read the Special Bulletin (No. 163, June 1927) on "Forest Planting in Michigan" by Alfred K. Chittenden of the Michigan State College of Agriculture. Planting work experiments have apparently been undertaken during the past thirty years at this institution. The present-day problem of the United States in connexion with timber supplies is well known and has been alluded to in NATURE on several occasions during the past year. The position of the several individual States in the matter is therefore not without considerable interest in Europe The author writes, "One of Michigan's greatest problems is that of replacing her forests. This is becoming increasingly important as the timber of the United States as a whole is being Nature, he says, if given a chance will restore the forests of her own accord, but this is a slow process; nor will the composition of the second growth consist of the most valuable species. If these latter are required, planting must be resorted to. The author regards the matter from a different view-point to that usually accepted in Europe. "Although trees," he says, "will grow on the poorest soils, they, like farm crops, will do better on richer soils. So, while the forests will probably ultimately be confined to the poorer classes of soils which will not be needed for agriculture, it is better to plant forests in the meanwhile on the best lands available for the purpose.' This may be the correct solution at the present time in a country where extensive areas of land are available, but would scarcely be applicable in England where the growth of food crops on all lands of suitable quality must be a first desideratum. The brochure is mainly confined to and intended for the planting of wood lots on farms. In several sections it deals with the questions of raising trees from seed in the nursery, the season to plant, field planting with costs, soil requirements, and the suitable species to make use of both from the point of view of soils and the uses to which the material grown can be put. Brief descriptions of the species advocated are given. The Bulletin

concludes with a note on the afforestation of sand dunes and the method of planting windbreaks and shelter-belts.

New Eocene Mollusca from Texas —An interesting paper on some new species of Mollusca from the Claiborne and Wilcox groups of the Eocene of Texas comes from the pen of Julia Gardner (Jour Washington Acad. Sci., vol. 17). Twenty-one new species and subspecies are described and figured on four excellent plates. The only freshwater form recorded belongs to the genus Planorbis, which has not been previously reported from the Eocene of Texas, and is represented by P. anderson, n. sp. It is fairly common at the single locality where it was found

New Silurian Pelecypod (Pycnodesma) from Alaska — Mr. Edwin Kirk places on secord a new pelecypod genus. Pycnodesma, from the Upper Silurian of Alaska (Proc. U.S. Nat. Mus., vol. 71, art. 20) It is a large massive shell, sometimes attaining a size of 12 inches across and upwards of 2 inches in thickness at the umbonal region. The author refers it to the Megalodontidæ and compares it with Megalodon and Megalomus, from both of which it differs in its hinge characters. His figure of the hinge shows its peculiar features, which are such as to raise the question whether, possibly, this new genus may not be an ancestral form of his earlier described Devonian Tanaodon (Nature, vol. 120, July 2, 1927, p. 25), although the author himself does not make the comparison.

DISCHARGE PHENOMENA.—Important quantitative contributions to the theory of glow discharges have been made by Prof. K. T. Compton and Mr. Morse in the September number of the Physical Review, and by Dr. J. Taylor in an Utrecht thesis presented on Sept. 28. The former have deduced a relation between the cathode constants of a discharge which is just self-maintained, and Prof. Townsend's 'ionization constants' for the gas. The new feature in their work is the use of the principle that the fields within the tube must be distributed so that there shall be a minimum dissipation of energy; Poisson's space-charge equation does not occur in the main analysis. Their predictions are verified as well as can be expected from the present meagre experimental data. Dr. Taylor has been more concerned with the initiation of the discharge, where he has been able to correlate the sparking potentials with the normal current-voltage curves, and those obtained when the supply of energy is restricted externally.

Stereographic Survey.—In the Geographical Journal for September, Major K. Mason describes, with maps, the results of his experiments in the Shaksgam with the Wild photo-theodolite. The instrument proved most satisfactory and the criticisms that are offered refer only to minor points of design and very superficial matters. The tests included an area already within the planetable survey of India, an area at the edge of the survey, to ascertain the value of the instrument for long distance reconnaissance survey, and an area without any control points identified for certain to find the limitations of the method for the revision of old maps. The plotting of the photographs was done on the Wild Autograph, which is designed to plot and contour four pairs of plates taken with the phototheodolite. Mr. A. R. Hinks describes this machine and explains its principles in the same issue. The method has proved so successful that the Swiss Federal Topographical Survey has decided to use it in the re-survey of the whole of Switzerland.

MEASURING QUARTZ FIBRES.—In the October issue of the Journal of Scientific Instruments, Messrs G. A. Tomlinson and H. Barrel, of the National Physical Laboratory, describe the two methods they have used for measuring the diameters of fine quartz fibres. If the fibre is placed in a parallel beam of white light and the deviations of the coloured bands seen on each side of the fibre are measured, then, on the theory that the fibre acts as a slit, its diameter can be calculated. Owing to reflection and refraction at the fibre, the results are not very accurate, but the method provides a simple means of testing the uniformity of the fibre by observing the bands as the fibre is moved along parallel to itself. The more trustworthy method is to clamp the ends of the fibre so that it is horizontal, and to hang a weight of about a milligram to its centre and measure the sag The elasticity of quartz is taken as  $5.18\times10^{11}$  dynes per sq cm. The arrangement is that adopted to determine the breaking stress in wires by s'Gravesande, Physices Elementa Mathematica " (1742)

A MECHANICAL MAXWELL DEMON.—Small particles are notoriously more difficult to examine when they are neutral than when they are charged, and although the distribution of velocities amongst groups of electrons and ions has been analysed frequently, it has hitherto been impracticable to do this satisfactorily for ordinary gas-molecules. A considerable advance in this direction is described by J. L. Costa, H. D. Smyth, and K. T. Compton in a recent paper in the Physical Review (vol. 30, p. 349). A shaft carrying two slotted wheels was rotated at high speed within a stout metal container, the space between the wheels being evacuated by a powerful diffusion pump. (las was fed into a lateral chamber, and those molecules the velocity of which had the appropriate relation to the speed of rotation and to the geometry of the apparatus, passed through gaps in both wheels and fell on the vane of a delicate radiometer. When the deflexion of the latter was plotted as a function of the rate of revolution, curves were obtained which agreed with those predicted on the assumption that the molecules had a Maxwellian distribution of velocities. The experiments were, however, difficult- in particular, the radiometer had to be used almost at the limit of its sensitivity—and it is unfortunately not yet possible to obtain the 'velocity spectrum' which was the original aim of the investigation.

THE IGNITION OF GASES BY HOT WIRES.—A recent publication (Paper No. 36) of the Safety in Mines Research Board (London: H.M. Stationery Office, 1927. Is. net) contains an account of a research carried out to discover whether the glowing filament of a two-volt miner's electric lamp-bulb might cause the ignition of mixtures of firedamp and air and thus constitute a source of danger in a coal-mino. The tungsten filaments of bulbs of recent manufacture burn at a high temperature (about 1500° C.) and, if breaking the glass did not fracture the filament, were found capable of igniting mixtures containing not more than about 12 per cent. of methane. With more than about 12 per cent. of methane. platinum wire of a given diameter, ignition can only occur within a narrow range of current, below which flameless surface combustion takes place. Above this limit, the wire fuses without igniting the mixture, providing it is less than 0.1 mm. in diameter. Heated tungsten wire, however, oxidises rapidly in the presence of oxygen, the temperature increasing until the metal burns with a bright flame of short duration but high temperature. This flame causes the ignition of firedamp. It is therefore recommended that the lamps should incorporate an automatic circuit-breaker operated by breaking the outer protecting glass.

# The University of Bristol.

NEW PHYSICS LABORATORY

THE University of Bristol not only owes its foundation to a member of the family of Wills. but also has since received a series of princely gifts from his two sons, Sir George and the late Mr. Henry Herbert Wills Of these none is more striking than the Henry Herbert Wills Physics Laboratory, formally opened on Oct 21 by Sir Ernest Rutherford before a distinguished company of physicists and of supporters of the University in Bristol and the surrounding counties. The laboratory through which Bristol may be expected to become increasingly important as a centre of physical research and teaching has arisen as the result of a gift of £200,000 presented in the years of future extension; pending this, an external non staircase is provided at its end. It contains four floors, together with one large and one small cellar completely underground In general the 100ms are arranged in units or multiples of units, in width 17 feet between centres. On the north side of the corridors most of the rooms are 26 feet deep, and on the south side 161 feet deep. The ferro-concrete floors have intermediate support on a single row of concrete pillars axially central in the building. The building is designed more or less as a shell, and internal divisions may be removed or rearranged as required.

The general scheme of this portion of the building

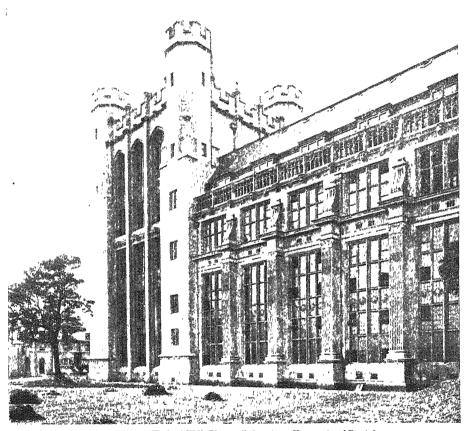

Fig. 1—Henry Herbert Wills Physics Laboratory, University of Bristol.

1919-20. Mr. Wills desired that this gift should be used mainly in the erection of the building and that the interest accruing in the meantime should provide for its scientific equipment and go towards the establishment of an endowment fund for its maintenance.

The building as designed is the first instalment of an extensive scheme of University buildings intended by the donor to crown the top of a hill overlooking the city, and to be a distinctive feature in distant views of the city. Until the whole scheme has been developed, either as Mr. Wills intended or on somewhat similar lines, the meaning of the design of this first unit, with its tower and reversed "L" shaped plan, cannot be fully grasped.

The long arm of the "L" is arranged with the view

is subject to alteration in later years as the work of the laboratory develops. At present it is as follows:

Ground Floor ... Research Rooms, Power Rooms, and Workshop.

... Research Rooms and Senior Teach-First Floor ing Laboratories.

Senior Optics and Junior Teaching Second Floor Laboratories.

... Library, a suite of Class Rooms, Third Floor Seminars, and Private Rooms.

On each floor one or more rooms are allotted for future extension and fittings are not yet provided; the necessary supplies are, however, brought to the rooms ready for distribution later as required. In particular, on the third floor advantage is being taken of space set aside in this way to maintain a close haison with the Department of Mathematics, which, it is anticipated, will occupy the greater part of this floor for some years to the mutual benefit of both subjects. On this floor a room 53½ by 26 feet, with a gallery, is allotted to the library, and will provide accommodation for many years for the growing needs of the two departments in this direction

An important bequest by Mr John Exley to the University College of Bristol in 1900 has provided the library with valuable sets of back numbers of leading scientific periodicals. The supply of these has since been maintained by annual grants which will be supplemented, owing to Council's decision to allocate to the Physics Library the income from a capital sum of about £1800 bequeathed to the University by

Miss Maria Mercer.

The short arm of the "L" contains two storeys, and includes two theatres, apparatus rooms, and cloak rooms. The larger theatre, on the first floor, contains seating for 300 as a minimum, but bench seats provide for a considerably larger audience on special occasions. Its blinds are electrically controlled. The smaller theatre is beneath it, and is provided with a minimum seating of 130. The acoustic properties of both theatres have received particular consideration.

Under the roof of each arm of the building there is a large loft suitable for extensive storage or, if need be, for any special experiment requiring an uninterrupted

length of space.

The junction of the two arms of the building is surmounted by a tower 64 feet square—In this there is a fourth floor containing two large rooms available for research. It is flanked by four turrets, one of which contains a vertical shaft. 4 feet by 3 feet, which goes to the bottom of the building, 90 feet below

In the general equipment of the rooms special regard has been paid to the wishes of the donor that the furniture and fittings should be of such a high quality as would relieve the University from expenses of repairs for many years to come. The changing needs of any scientific laboratory in these days of rapid advance have, however, been constantly kept in mind, and nothing has been done to diminish the flexibility of the equipment essential to meet new conditions as required. In the provision of gas, water,

and electricity in the various rooms the rival claims of the overhead system and the floorduct system have been carefully considered. It was telt that in the main teaching laboratories, where the presence of a few fixed tables distributed over the floor has no meonvenience, the floorduct system has fewer disadvantages, and for this reason it has been adopted. In the research rooms, many of which are relatively small, the supplies of gas, water, and alternating current are conveyed through the rooms in floorducts, and those of direct current of various voltages by bare wires overhead At the same time, a horizontal duct with creeping way is provided in the roof of the main corndors. This not only serves the purpose of a vitiated air duct in the ventilation system, but also gives means for rapidly laying any temporary cable or piping as required to any room

For the supply of compressed air and of vacuum, the unit system has been preferred to that of general distribution. Any worker who requires either of

them has it thus under his own control.

The University Council has been fully alive to the necessity for funds for apparatus and for additional personnel. It has, however, aimed at avoiding the inistake of installing special equipment of a costly character before men are available to use it, and equally that of creating a number of new posts before funds are available for the provision of the apparatus necessary for their investigations. In apparatus, therefore, immediate provision has been made for the researches of the existing staff, and for the present requirements in teaching, while a small reserve fund has been set aside to form a nucleus for future needs

In the provision of personnel the Council has found its way to meet some of the new requirements by the creation of certain new posts. Thus, as has been already announced in these columns, Dr. J. E. Lennard-Jones has been appointed to a professorship in theoretical physics and Dr. L. C. Jackson and Dr. H. W. B. Skinner to Henry Herbert Wills' research fellowships.

If, however, the laboratory is to be put to the full uses that its donor desired, further additions to the personnel and equipment will be necessary, and it is hoped that both will soon be forthcoming.

# The Velocity of Light.

By M. E. J. GHEURY DE BRAY.

MOST tables of determinations of the velocity of light contain misstatements which seriously detract from their utility. Moreover, there seems to be no table available giving a fairly complete summary of the work which has been done to ascertain the exact value of this most important constant.

The following table has been compiled, from the original communications contributed by the investigators themselves, for the purpose of meeting this want. It contains every value which has been deemed by the author of the observations to be worthy of being stated as the result of a completed series of experiments, in the course of the work which ultimately led to a final value adopted as representing best the result of this work.

The history of the quest for the value of the velocity of light is conveniently divided into three periods, and the table has been accordingly divided into three sections, in a manner which the headings render self-explanatory.

The letters TW refer to the toothed wheel (or 'eclipse') method and RM to the revolving mirror method. These two methods which, although both

of French origin, have become characteristic of European and American practice respectively, are classical and need no further explanation here. References to the original papers, etc., are given after the table, with brief remarks whore necessary. In most cases the data have been left in the form in which they were given by the investigator or by the author of the paper, etc., himself (except that all the values of the velocity have been expressed in the same unit: kilometres per second), even when a modification suggested itself, such as when the velocity in air only was given, or when the velocity was stated with a degree of accuracy which is evidently unwarranted owing to the residual uncertainty attaching to the determination.

Not infrequently it has been impossible to ascertain the average date of a series of experiments, and in such cases, after careful consideration of the available evidence, a date has been adopted which appears to represent fairly the most probable position of the observations on the chronological scale. The values being tabulated in chronological order, it follows that mean values (to which a mean date has been assigned)

No. 3025, Vol. 1201

are placed in the table before some of the determinations concurring in its formation. The determination of a velocity being dependent on the value of the unit of time, and the latter being determined by the time of rotation of the earth, which is suspected of variation, it is thought that the exact date may become useful in the view of further advance in knowledge, and it is desired that the table be no more found wanting in this respect than in others.

It is seen from the table that there are seven, and only seven, determinations which may be considered

as trustworthy.

(In the discussion below, the abbreviated references are to publications listed at the end of this article)

not stated. Harkness also gives as Foucault's value 298,574±204, stating that this is the final result obtained from 80 observations made on Sept 16, 18 and 21, 1862. This information is derived from the "Recueil des Travaux Scientifiques de Léon Foucault," Paris, 1878, which gives (pp. 224 and 225) the dates and numerical results of Foucault's observations on the velocity of light, made between May 22 and Sept. 21. The value still given in this "Recueil," however, is the same as that given in the Comptes rendus, namely, "298,000 kilometres par seconde de temps," and it is not apparent how the value given by Harkness is obtained from the data given in the 'Recueil."

(1) [1, vol. 29, 1849, p. 90] and (2) [1, vol. 55, 1862, p. 501] are admittedly but rough approximations, the experiments being intended to ascertain the possibilities of the method. The unreliability of the second determination may be estimated from the fact that the deflexion from which it was deduced was only 0.7 millimetres (ii, p. 233). The first result is undoubtedly far too high, and the second is much too low. There appears to be little to choose between the two, although the second method is more likely to be the less maccurate, being simpler in technique and of easier application. One seems justified in taking their mean.

W. Harkness (Washington Observations for 1885, Appendix III. p. 29, under the heading "Velocity of Light in racuo," gives as being Fizeau's value "70,948 lieus (sic) of 25 to a degree = 315,324 kilometres." The former value is not the value in vacuo, and how the equivalent in kilometres was obtained is

(3) [111, p. A 298, footnote] was rejected by Cornu as being affected by serious systematic errors

(4) [in and i, vol. 79, 1874, p. 1361]. In the Annales (p. A 293) the velocity is given as 300,350 in air, the additive correction to vacuum being 82; the final velocity is 300,400. In the Comptes rendus (p. 1363) the velocity in air is given as 300,330, and the final velocity in vacuum, obtained by multiplying by 1.0003, is 300,400. Cornu, therefore, evidently concerns himself with four significant figures only. Newcomb [vib, p. 202] gives wrong years for these determinations, and the errors are copied (xi) by Michelson and Preston ("The Theory of Light," 1901 ed., p. 511).

(5) [iv, vol. 87, 1876, col. 123]. Cornu protests strongly against the treatment his results have suffered in Helmert's hands [ii, p. 227, footnote]. The probable error is estimated by Todd

[v, p. 61].

(6) and (7)  $[v_1a]$  The first value was discarded by its author owing to its large probable error (loc cit., pp. 115-116) compared with the greater accuracy of the subsequent determination. The latter was given as 299.944 - 51, and rounded to 299.940 = 50 (loc. cit, p 141). A correction was announced later on [vic. p 244], reducing it to 299,910 - 50. Newcomb, when mentioning this correction, misquotes the original value, giving it as 299,942 [vib, p 119, footnote]. Todd [v, p. 61] refers to this value as given in the 'corrected slip,' but gives 299,930, no confirmation could be found

(8) and (9) [vib] are declared by Newcomb to be doubtful owing to the presence of systematic errors. "The preceding investigations and discussions seem to show that our results should depend entirely on the measures of 1882" (loc. cit., p. 201). He does not trouble to reduce them to vacuum, and he does not mention their probable errors. It is only with evident reluctance, and to avoid criticism (loc. cit, p. 201-2), that he includes them in a mean value (11), with (12) which is clearly the value which he favours

as most reliable (loc. cit, p. 202)

(9) [vii, p 231]. Two distant reflectors, in line with the source of light at the observing station, were used so as to have two images. Other experimental features, however, were detrimental to the obtainment of good results, and this determination was severely criticised by Newcomb [vi b, p. 119] and by Cornu [ii, p. 229]. The result is given by the authors with an unwarranted accuracy (loc. cit., p. 269), but they give no probable error.

(13) [vi c]. The agreement between this value and Newcomb's last determination (d), obtained practically simultaneously, is worthy of remark; it seems to show that the accuracy was greater than the probable errors

seem to indicate

(14) [i, vol. 131, 1900, p. 731], and (17) [i, vol. 135, 1902, p. 881] were evidently announced as soon as a preliminary reduction had been carried out. Their average (16) is given in the second communication (p. 883), and is generally quoted as Perrotin's final value, although these results were considerably modified in the course of the final discussion (vide infra, (15)

and (18)).

(15) and (18) [viii]. Incredible as it may seem, this final discussion of the experiments first reported in the Comptes rendus (vide supra, (14) and (17)), makes no mention whatever of the results mentioned in these first communications. It is necessary to compare the observations themselves in order to ascertain that (a) and (b) are deduced from the same first series of observations, while (d) and (e) are deduced from the second series. The confusion is increased by the fact that (e) is so nearly identical with (a) that the latter seems to be the former rounded off, while they are actually obtained from two different series of observations over different bases. Prof. Michelson did not avoid this pitfall, and quoted Perrotin's final result as having been obtained over the shorter base instead of the longer one [x and xiii].

(19) [ix a, p. 256] was first given as 299,820, but a correction given later on [ix b, p. 2] reduced it to 299,802. It is given separately here, although, ultimately, it was 'lumped up' with others to obtain a mean, because it was evidently deemed by its author to be of sufficient accuracy to be published at once, which was not the case with any other pre-

liminary results obtained before.

(20) [1x b, p. 1] is the most accurate value yet published. It is the average of several series of observations made with multi-facet mirrors, all of which are in agreement within  $\pm 1$  km./sec.

(21) [ix b, p. 12] is announced as being in progress;

the base is the longest ever used, Perrotin Intherto holding the record. It is expected to be accurate to within I kin /sec

The following values have also been mentioned by certain authorities, no confirmation having been

obtamable

(22) [x and xiii] In the "table of results of the more important investigations to date," Prof Michelson gives for his own results (presumably from the observations made in 1878-1882) the value 299,895. It is not known how it is derived. It is not the

average of (a), (b), and (c)

(23) Abraham and Sacerdote ("Recueil de Constantes Physiques," Table 166) give 299,890 as having been obtained by Michelson in 1902. No determination appears to have been made by Michelson at about that time, but, in that year 1902 he published a paper [xi, p 6, and xii, p 334] in which he adopted this particular value as the most probable estimate to date, being an average of the results obtained by Cornu ("discussed by Listing," vide infra), Newcomb, and himself. Is this the origin of the value given in the "Recueil"?

(24). A value 299,990, alleged to have been obtained by Listing from a rediscussion of Cornu's observations is mentioned by Newcomb [vi b, p. 202], by Michelson, quoting Newcomb [xi and xii, p. 333], and by Preston (loc. cit., p. 511) also quoting Newcomb. No trace of such a discussion by Listing could be found, but Helmert [1v, vol 87, 1876, p. 123] obtains precisely this value 299,990 by rediscussing Cornu's results. This value, obtained by Helmert, is quoted correctly by Michelson [vi a, p. 144], by Todd [v, p. 61] and by Cornu [ii, p. 227]; it only masquerades as Listing's in Newcomb's Report and in later works quoting or copying Newcomb. Occasionally, however, Michelson refers to this value as Listing's even when referring to another work in which it is attributed to Helmert [xii, p. 334, 1. 33]! As shown above, Newcomb made several errors of transcription, or misquoted from memory, and these were copied indiscriminately by Michelson and Preston. The, evidence is fairly strong in favour of Newcomb attributing wrongly the value to Listing (who had just published a paper [iv, vol 93, 1878, p. 369] on the solar parallax ("Finige Bomerkungen die Parallaxe der Sonne betreffend"), and that Listing's discussion of Cornu's results is non-existent. Later [x and xiii], Michelson gives Cornu's result as 299,950. This is neither Cornu's, nor Helmert's, nor "Listing's," as hitherto quoted by him and others after Newcomb; what it is could not be ascertained. It would be highly desirable that the confusion already existing should be prevented from spreading by the exertion of a little care in giving the origin of any information which cannot be traced directly to its authentic source.

# The Tenth International Congress of Zoology.

F, as many contend, the chief value of these international gatherings is that they bring into personal touch the scattered workers in a single field or the larger number of workers in diverse but allied fields, then the tenth Congress of Zoologists, held in Budapest on Sept. 3–10 must be pronounced a distinct success. In spite of the clash with the Congress of Geneticists at Berlin, the British Association, and the meeting of Swiss Naturalists, there were registered no fewer than 862 members, though not all actually attended; those who did came from every civilised country north of the equator, and included delegates from 183 universities, academies, museums, and learned societies. The Governments of 24 of those countries were represented by 48 official delegates, those of Great Britain and China being apparently alone in declining the invitation. So far as the British Empire was concerned, the situation was saved by the appointment of Lieut.-Col. R. B. Seymour Sewell, I M.S., to represent the Government of India. Considering that the Congress was opened in the presence of the Minister of Education, Count Kuno Klebelsberg, and the Ministers or other official representatives of the leading Powers, and considering that on subsequent occasions selected delegates were received and entertained by the Regent and by Count Klebelsberg, it did seem to the British zoologists present that they might have been placed by their Government on a level with their distinguished colleagues from Turkey and Czechoslovakia.

This attitude of the British Government made it seem a shade ironical that the President, Prof. Géza Horváth, should have chosen the English language for just that section of his opening address which set forth the aims and results of applied zoology, the fight against the insect and mainmalian enemies of our forestry and agriculture, and the relations of zoology to medicine. Speaking in French, the president sketched the work of the Permanent Committee since the Monaco Congress in 1913, and deplored the death of two of its members, Edmond Perrier and Raphael Blanchard. In German he alluded to the results of experimental genetics and cytology and the help that modern zoology received from chemistry and physics. Finally, in Italian, he dwelt on the difficulty that specialisation placed in the way of a harmonious synthesis, and emphasised the service rendered by such a congress in knitting up the several lines of

This specialisation, coupled with the great diversity of the 260 communications presented at the general meetings and to the nine sections, makes it difficult to give a general survey of the scientific proceedings. One may set aside the laborious week spent by the Commission on Nomenclature and the animated but futile discussion in the section on that subject, for the main decisions will shortly be communicated to NATURE. One may also, for the immediate purpose, eliminate the section of experimental cytology, which came in rather as an annex to the Congress with the declared and afterwards fulfilled intention of budding off as an independent Congress. The zoology that was left appeared as a very different kind of science from the morphological and systematic zoology of the earlier meetings. The animal and all its parts down to the individual cell are now viewed less in their structural than in their functional aspect. A chord based on this note was struck by the four speakers independently selected by the organising committee to address the opening session.

Prof. R. Hesse, of Berlin, spoke on "The Ecology

of Animals: its Aims and Methods," defining

ecology as that branch of biology which considers life in relation to its environment. It provides an analysis of the struggle for existence, and its goal is the recognition of the 'Epharmonie,' that is to say, those characters which bring the creature into unison with its environment. A causal explanation would not, said Dr. Hesse, be attained without a more exact knowledge of animal chemistry. Dr. Bather, of the British Museum, speaking as a palæontologist, put to the systematist the question: Quo vadis? In the attempt to adapt a classificatory system, constructed with a different object and on a dissimilar basis, to a representation of phylogeny, systematists had got into a tangle. Greater recognition of similarities due to environment and their expression as classificatory 'grades' might save the situation. The adaptive dynamic characters of an organism were at least as important as the inherited, static characters. Dr. Charles Gravier, of the Paris Museum of Natural History, provided a concrete example of such a study. ın his account of "La phase pélagique de la vie des annélides polychètes à l'époque de la maturité sexuelle," and described the pairing-dance of the Palolo worm, as observed in the sea by means of a specially constructed lamp. Finally, Prof. R. G. Harrison, of Yale University, spoke on the status and significance of tissue culture. While the isolated cell dies and therefore cannot be observed, a cell-complex cut from the organism could be kept alive for an indefinite period. Carrel, for example, had kept the heart of a chick embryo alive since 1912. The study of living tissue would lead to a knowledge of the finer structure of protoplasm and of its regeneration. Thus the growth of nerve-fibres predicted on theoretical grounds by Ramon y Cajal could be clearly seen in a tissue-culture. The practical importance of tissue-culture lay in the help it could give to the fight against cancer.

To follow this theme—the organism as a living entity, working in harmony with its environmentthrough all the variations and illustrations submitted to the sections is impossible here. One can but point to a few of the papers read at the general meetings. In the first of these Prof. H. Spemann, of Freiburg 1. B., summarised the novel and important researches of his laboratory on what he terms "organisers" of animal development, a subject on which we hope soon to hear him in London. At the second session Dr. James Ritchie, of the Royal Scottish Museum, lectured on "The Influence of Man on the Develop-ment of Faunas." One of the effects on which he laid stress was the gradual killing off of the larger animals, with the result that the fauna of the world was assuming a more uniform character. At the same session Prof. A. Wandel, of Toulouse, directed attention to what he termed "Geographical Parthenogenesis," that is, the existence of species normally with sexual reproduction which in certain regions are strictly parthenogenetic, e.g. North European races of certain crustaceans, flies, butterflies, and other insects.

The third meeting listened to a most interesting lecture by Prof. K. v. Frisch, of Munich, on the senses and 'speech' of bees; to some new observations by Dr. G Brandes, of the Dresden Zoological Garden, on the life of the orang-utan, to an account by L. R. Natvig, of Oslo, of the breeding of Reindeer in Norway, where they number 135,000, and of the methods of fighting their parasites; to the description by Prof. P. Buchner, of Greifswald, of the symbiosis obtaining between certain wood-eating insects and fungi and infusoria; and to an account of some new experiments by Prof. Gilbert Rahm, of Fribourg,

which showed that life-processes could be entirely suspended in certain organisms without danger to life At the fourth session a large audience gathered to hear Prof. Voronoff, of Paris, and his pupil, Dr. Nemes Nagy, of Budapest, but had first to listen to Prof. Novikoff, of Prag, on the value of a study of analogy, and to Dr J Ettl, of Budapest, on the practical results obtained with human subjects by the regeneration and transplantation of tissue, the most remarkable being those cases in which bone was transplanted But the most applauded lecture of the Congress was that by Dr. Canti, of St. Bartholo-mew's, which had to be given three times. Dr. Canti's highly instructive films showing the growth of tissue and the actual division and mitosis of cells, have been shown more than once in London, but on this occasion he added films in which the results of irradiation by radium on the living tissue were clearly demonstrated. Dr. Canti had the honour of showing his film to Count Stefan Bethlen and Count Géza Telekı.

During the Congress members had the opportunity of visiting various museums and institutes, such as the National Museum, the Ornithological and Geological Institutes, the Zoological Garden, and the magnificent museum for agriculture, forestry, and land development, admirably adapted to the Hungary of pie-War days with its mines, its quarries, and its forests, but a melancholy reminder to the Hungary of to-day. The present wealth of Hungary lies in the heids and flocks of the great plain, which members had an opportunity of seeing on an excursion to the Hortsbagy Puszta, and in the vigour of its people all inspired with an intense desire to maintain the highest level of civilisation, as exemplified in the clinics of Debrecen University and the Biological Institute on Lake Balaton.

Small space is left in which to record the kindness and hospitality shown to foreign members by the Government, the Municipality of Budapest, directors of the various institutes, and indeed all with whom the visitors were brought into contact. pleased all to hear at the concluding meeting that the president, Prof. Horváth, had just received the Hungarian Cross for Distinguished Service of the Second Class.

The next meeting of the Congress is to be in Padua in 1930, under the presidency of Prof. Paolo Enriques. Prof. L Joubin (Paris) has been elected president of the Permanent Committee, with Dr. M Caullery as Secretary.

# University and Educational Intelligence.

BIRMINGHAM.—A legacy of £2000, bequeathed by the late Mr Christopher Collins, is to be added to the

Biological Building fund.

On his retirement from the chair of physiology, Prof E. W. Carlier has presented 120 volumes to the library of the Physiology Department. Prof. Carlier has also given to the department a most valuable set of 3000 microscopic preparations from his private collection, together with a number of teaching diagrams.

The Huxley Lecture is to be delivered on Thursday, Dec. 1, by Prof. A. S. Eddington, Plumian professor of astronomy and experimental philosophy in the University of Cambridge.

Among changes of the lecturing staff are the followmg: Resignations—Mr. H P. Dean (mechanical engineering), Mr. L. Eastham (zoology), Mr. J. P. Rees (mining), Mr. O C. Elvins (oil engineering). Appointments: Mr. D. A. M. Sandifer (mechanical engineering). gmeering), Mr. D. L. Gunn (zoology), Dr. W. Hancock (mine rescue work), Mr. R. Glossop (metal mining).

Cambridge —For the seventh year in succession. Truity College announces the offer of a Research Studentship open to graduates of other universities who propose to go to Cambridge in October next as candidates for the degree of Ph D.—The value of the Studentship may be as much as £300 a year if the pecuniary circumstances of the successful candidate require so large a sum. Applications must reach the Semor Tutor not later than July 1, 1928 — The same College offers, as usual, Dominion and Colonial Exhibitions to students of Dominion and Colonial Universities who wish to go to Cambridge next October as candidates for the degree of B A., M Litt. M.Sc, or Ph D The Exhibitions are of the titular value of £40, but their actual value is such sum (if any) not exceeding the titular value as the College Council may from time to time hold to be justified by the Exhibitioner's financial circumstances. If it is made clear that the financial need of an Exhibitioner cannot possibly be met by the payment to him of the full amount of his titular emolument the Council has power, it it sees fit and if funds are available, to award him an additional payment—Candidates must apply through the principal authority of their university, and applications should reach the Senior Tutor (from whom further particulars may be obtained) by July 1,

Edinburgh.--Dr C. H. O'Donoghue, professor of zoology in the University of Manitoba, Winnipeg, has been appointed to a senior lectureship in zoology, and Miss Irene A. F. Hilton, to a junior lectureship in zoology.

MANCHESTER.- Dr R. B. Wild, who has recently retired from the Leech chair of materia medica and therapeuties, has made a gift of £250 for the endow-

ment of a prize in pharmacology.

The following appointments have been made Assistant lecturer in metallurgy, Mr. W Cartwright, Assistant lecturer in geology, Dr. M. B. Hodge; assist-Assistant fecturer in geology, 12. ... C. A. Methaughey; ant lecturer in bacteriology, Mr. C. A. Methaughey; demonstrator in bacteriolgy, Mr. E. St. G. Gilmore, demonstrator in pathology, Mr. H. L. Sheehan; demonstrator in chemical technology, Mr. C. Chew

Sheffield - The University Council has made the following appointments: R. Cooper, assistant lecturer in mathematics; Dr. F. C. Chalklin, assistant lecturer in physics; and Miss Flora M. V. Brown, part-time assistant lecturer in botany.

THE Committee of the Leplay House Educational Tours Association has arranged a visit to Sicily during the coming Christmas vacation to study the history of the Island, mamly through its architecture, under the leadership of Mr. Stanley Ramsey. A regional survey meeting will be held at the Collège des Ecossais, Montpellier, at the invitation of Prof P. Geddes; the studies will be under the direction of Mr. George Morris. Full particulars can be obtained from Miss Margaret Tatton, Leplay House, 65 Belgrave Road, Westminster, S.W.1.

Mr. H. G. Beard, research assistant in the Department of Colour Chemistry at the Technical College, Huddersfield, has been appointed research chemist at Woolwich Arsenal. Mr Beard has received the whole of his chemical education at the Huddersfield Technical College, and for the past four years has been working under the supervision of Dr. H. H. Hodgson, head of the Department, with whom he has been the joint author of numerous papers published by the Chemical Society and the Society of Chemical Industry.

# Calendar of Discovery and Invention.

October 23, 1820.—The general substitution of wrought-iron rails for cast-iron rails in the early railways was brought about by the invention of John Birkinshaw, manager of the Bedlington Iron Works. Rectangular bars were first used, but on Oct 23, 1820, he patented the T form of rail, whereby increased bearing and strength were obtained with the same weight of material. He afterwards devised the fish-bellied rail which was used in the Stockton and Darlington Railway

October 24, 1851.—Lassell, whose discovery of Neptune's single satellite on Oct 10, 1846, has already been referred to, prosecuted his search for other satellites for many years, but without success until Oct. 24, 1851, when he discovered the third and fourth satellites of Uranus, and they were named

Ariel and Umbriel.

October 25, 1795.—At the height of the revolutionary period in France the various academies in Paris were suppressed, and for two years men of learning had no recognised status or meeting-ground. From the rums of the academies, however, sprang the Institut National, inaugurated on Oct. 25, 1795 (3 Brumaire, an iv.). The Institut to-day comprises five academies, of which the Academy of Sciences is one. At first it had various homes, but Napoleon housed it in the Collège Mazarin, built in 1663–70, as the Collège des Quatre Nations Réunies. Its anniversary meeting during the restoration was held on April 24, and under Napoleon III. on Aug. 19, but since 1870 it has always been held on the original day, Oct 25. One of the functions of the Institut is that of "registering discoveries and perfecting arts and sciences."

October 25, 1847.—At a time when photography, though in its infancy, was attracting considerable attention, Niepce de Saint-Victor, an officer in the French Army, following up the discoveries of his uncle, Nicephore Niepce and Daguerre, discovered a method of photographing on glass. He gave the first account of his process in a paper communicated to the Paris Academy of Sciences on Oct. 25, 1847.

October 26, 1711.—The Board of Visitors which

October 26, 1711.—The Board of Visitors which visits the Royal Observatory at Greenwich annually was first appointed by Queen Anne in December 1710, its origin being traceable to the unfortunate misunderstandings that prevailed between Flamsteed and some of his contemporaries. Apparently the first time the Board met the Astronomer Royal was in the rooms of the Royal Society in Crane Court on Oct. 26, 1711. The Board was empowered to demand from the Astronomer Royal a copy of his annual observations and to inspect his instruments. Flamsteed, however, had constructed some of the instruments at his own cost, and it is stated that when on this occasion he was requested to report on his instruments, he declared they were his own and he would suffer no one to concern himself with them.

October 27, 1806.—Napoleon, who had a keen appreciation of the value of scientific discoveries and inventions, often conferred rewards for such work. One instance was his recognition of the invention of the loom for figured weaving by Jacquard, to whom, by a decree dated from Berlin, Oct. 27, 1806, he gave

a pension of 6000 francs.

October 29, 1852.—One method of making electrotypes was that patented by Paul Pretsch, Oct. 29, 1852, under the name of photo-galvanography. From a transparency a gelatin relief image was obtained, which, being made conductive, was coated with copper. The copper shell was then backed with type metal to produce a printing plate.

#### LONDON.

Society of Public Analysts, Oct. 5 -A Chaston Chapman. The oil of Centrophorus granulosus liver oil of the Portuguese shark 'barroso' (Centrophorus granulosus) contains the unsaturated hydrocarbon, spinacene, an alcohol probably identical with the batyl alcohol found in Japanese shark oils, a liquid alcohol (selachyl alcohol,  $C_{21}H_{10}O_3$ ), cholesterol and glycerol (0 5-0.6 per cent ), together with stearic, palmitic, and oleic acid, and possibly smaller proportions of other saturated and unsaturated fatty acids —W. R Schoeller and E. C. Deering: The separation of titanium from tantalum and niobium. The method is based on the dissociation of the soluble tartaric complexes of the metallic acids by a mineral acid, the earth acids are precipitated, whilst the titanic salt remains in solution The results as yet obtained are approximate—C L. Hinton and T. Macara. The determination of aldose sugars by means of chloramine-T, with special reference to the analysis of milk products Each molecule of chloramine-T is equivalent to two atoms of iodine, both in the oxidation of sugar and in the final liberation of rodine on acidifying. The oxidation proceeds more slowly than that with alkaline iodide solution The most suitable conditions for the oxidation of dextrose and lactose have been worked out, and the extent of the slight oxidation of sucrose and lævulose under standard conditions has been determined Under the conditions specified, the action of chloramine-T on the non-sugar constituents of milk serum does not cause an error greater than 0.4 per cent. of the total lactose.

### PARIS.

Academy of Sciences, Sept. 12.—Jean Perrin. Valency and addition compounds. A summary of various views of electronic valency with some applications to organic compounds.—Mme. Ramart-Lucas The mechanism of molecular transpositions. An application of the conception of inonoelectronic linkage, or semivalence, to the phenomena of intra-Pierre Viennot: molecular transpositions. geology of the neighbourhood of Hasparren (Basses-Pyrénées).—G Ollivier: Culleria monoica, gameto-phyte of Aglaozonia chilosa —A. Lebediantzef. The reaction to desiccation of different types of soils in the tchernozem and podzol zones of European Russia. -R. Wilbert: An infectious disease of the chimpanzee, transmissible to man. This disease, which appears to be due to a spirochate, caused the death of 32 chimpanzees out of 33. The author caught the disease but recovered. His blood contained the same spirochæte as the affected chimpanzees, and its inoculation into a chimpanzee caused its death.

Sept. 20.—A. Lacroix: The chemico-mineralogical characters of the tertiary intrusive and volcanic rocks of North Africa.—G. Bigourdan: The third general assembly of the International Geodetic and Geophysical Union. An account of the meeting held at Prague on Sept. 3–10, 1927.—T J. de Seze: The degree of accuracy of common formula of resistance of materials.—Mme. Christine Ladd-Franklin: The visible radiation arising from stimulated nerve fibres.—René van Aubel: The presence of crystallised uraninite in the uraniferous deposits of Kasolo (Katanga).

# Natural Science in Adult Education.

THE growth of knowledge, and the necessary limitation arising from the age and duration of school life, create an ever-widening gap between the actualities and possibilities of education. The boy or girl who leaves school to enter some profession is usually able to secure suitable further training in part-time classes at a local technical school or college But there are many men and women who have no need of special training, or have already obtained what they require, but have intellectual needs which call for satisfaction. They read newspapers and books; they are members of clubs or societies; they acquire an interest in social or political or economic problems, or in philosophy, or literature, or science, and they enter into eager controversy on the problems of the day. Those who possess depth of feeling or understanding, whose interests are not the languid ephemeral interests of the man in the street, realise the need for wider and deeper knowledge, for training in methods of study, for direction of reading, and for friendly guidance and criticism.

Training of this kind has been provided for many years in University Extension Courses, in the last quarter of a century in classes under the Workers' Educational Association, and more recently in the London Literary Institutes. The work has become an integral part of national education. It is aided by Local Education Authorities, and has acquired sufficient magnitude and importance for Treasury grants to be administered under a separate set of regulations—the Adult Education Regulations of the Board of Education.

The training in these classes exists in response to a distinct demand. This demand is usually for something which bears upon the wider aspects of intellectual life rather than upon the narrower requirements of an occupation It represents a desire for knowledge for its own sake, a desire to share in the intellectual heritage and to understand some aspect of the material or intellectual progress of the generation in which they live. It arises at a later age than that at which students pass into technical schools or universities for professional or occupational study; and however complete may be the facilities for the continuous full-time education of all who appear when young to be capable of profiting by it, the need for this kind of training will remain.

From this point of view the field of adult education is not limited to economics, to history, or to literature, but extends over the whole field of

human knowledge; and we welcome the interesting and instructive report 1 of the Adult Education Committee recently issued by the Board of When the Committee commenced its Education labours in 1921, most of the classes were in economics and history. At the first meeting, Mr Fisher, then president of the Board, expressed the hope that the Committee would "investigate the possibility of extending the range of studies in the adult education movement" As a result of its observations the Committee is able to note in 1927 "a distinct tendency in this direction" particular, "classes in English Literature have increased greatly both in numbers and in proportion to the whole," and "the growth of interest in Music and the Drama has also been considerable " But the Committee deplores the fact that "there has been no corresponding growth in the number of classes in Natural Science"

After reviewing the value of natural science as a humane study, in everyday life, and in industry, the report discusses the evidence of an interest in the subjects which fall under the vague yet comprehensive title. There appears to be some doubt whether the interest is now so great as it was fifty years or more ago; but the conditions of life are so different that no comparison is of much value. much greater proportion of young people obtain instruction in the elements of natural science at school; a greater number of students attend technical schools in which the instruction is far more specific and highly organised, far less academic or of general interest, than it was even twenty-five years ago; local travelling facilities have immensely improved, and the means of employing lessure are more varied than they used to be; Local Education Authorities are more independent of external aid, and inclined, on the ground of expense, to concentrate on what appears to be the primary function of the local technical school. The pioneer work of the famous men who upheld the banner of science in the last century can scarcely be compared with that expected in a tutorial class conducted by the Workers' Educational Association to-day. The circumstances have altered and the aims are not the same.

In regard to the existing provision, we note that in 1925-6 "the number of courses in Natural Science recognised under the Adult Education Regulations was 47 out of a total of 1224; the number of students attending these courses was 935 out of a total of 26,806." These figures do

1 "Natural Science in Adult Education" Paper No 8 of Adult Education Committee (London: HM Stationery Office, 1927)

not include non-vocational courses promoted la Local Education Authorities. From such statistics as the Committee has been able to obtain it concludes that "the study of Natural Science being neglected in comparison with other studies."

The courses described or commented upon cover a wide field, but are conveniently grouped under biology, geology and geography, and the physical By reason of their human interest, sciences classes in biology have been especially successful and in some cases have been continued for four years or more. Very little apparatus is required, and the classwork is supplemented by field excursions and visits to museums. Geology and geography also call for little special accommodationor equipment. The requirements for physical science vary widely with the branch chosen, but even where laboratory work is not necessary there may be a need for a degree of mathematical knowledge not usually possessed by adult students.

Apart from differences of method, advocated by different witnesses, there appears to be a greater similarity of content, and more uniformity of aim, in courses in biology and geography than in physical science. The former almost invariably suggest a wide view of the universe and of the evolution of living things; the latter vary from "Chemistry of Everyday Life" or "Chemistry in the Home" to "Modern Views of Matter" and similar subjects.

There is an implication on page 20 of the report that biology is more widely studied in Tutorial Classes and the physical sciences in Extensior Classes; and on page 52 the mathematical and experimental requirements are referred to it support of the view that physical science is lessuited "to the method of a Tutorial Class." Busince the original condition of the Adult Educatio Regulations that "the instruction must aim at reaching, within the limit of the subject covered the standard of University work in Honours," now only applies if the subject is such as to make that a possible aim, the suitability of physical science for a Tutorial Class seems to depend mainly upon the syllabus and the teacher

The report recognises the need for competent teachers, and advocates the appointment by the universities of staff tutors for this work. It complains that the high degree of specialisation at the universities does not provide men with the requisite breadth of training. On this matter we are at one with the Committee. But something more than breadth of knowledge is required. The man who is to attract and retain adult student

requires personality. He must have sympathy and understanding, and be able to realise the content and attitude of mind of those who come to him for instruction and inspiration He must have such et grip of his subject that he can break down traditional and academic barriers between branches of knowledge-barriers which, while not inappropriate in a full-time university course, are unnecessary and frequently out of place in a course which will rarely permit of more than 150 hours' instruction, he must know not only how to learn himself, and how to present his subject attractively, but also how to train his student to learn for themselves. Also, if he wishes to enjoy, and help others to enjoy, the pleasure of learning, if he wants to feel, and make others feel with him, the exquisite thrills which accompany mental growth, he must have a command of language which will enable him to clothe the dry bones of fact and theory, and make them live.

While we share the desire of the Committee to see an increasing number of classes devoted to the study of natural science, we do not desire a rate of increase greater than that of the supply of competent teachers. For if the teaching is to be humane, if it is to reveal the patient and accurate observation involved in scientific investigation, if it is to train judgment, if it is to create awe and reverence for the wonders of the universe, it must be based upon qualities for which academic attainment is neither a measure nor a guarantee.

# X-Ray Analysis.

Die Verwendung der Röntgenstrahlen in Chemie und Technik: ein Hilfsbuch für Chemiker und Ingenieure. Von Dr Hermann Mark (Handbuch der angewandten physikalischen Chemie in Einzeldarstellungen, herausgegeben von Prof. Dr. Georg Bredig, Band 14.) Pp. xv + 528. (Leipzig: Johann Ambrosius Barth, 1926.) 48 gold marks

DESPITE the recent large output of books dealing with X-rays and their applications, this addition is a very welcome one. Himself a leader of the German school, Dr. Mark has brought to his task a quite exceptional knowledge of the theory and practice, and it would be difficult to find any one better fitted to produce a sound as well as a helpful text-book of this subject. Issued as a volume of a new handbook of applied physical chemistry, it is described by its author as a book intended for the guidance of chemists and engineers. It is more than this, it is a book to be possessed by all who have to deal with X-ray problems.

The main object is to introduce the reader to, and train him in the methods of, X-ray crystal analysis, and for such an end to be successful it is necessary to discuss the nature and properties of X-rays, the theory of the older crystallography, and then the applications of X-rays to the problem of the solid This is briefly the general scheme of the In the earlier chapters the methods of book production of X-rays are described in a very practical way. Details and working instructions of the essential apparatus are given, details sufficient to enable even the inexperienced to select a suitable equipment and to know in advance the difficulties he is likely to meet and how they may best be over-There follows an account of X-ray spectrometers and spectroscopy, and of the most important properties of the rays themselves, with very complete tables of wave-lengths and other useful data.

In the same masterly way, the subject of crystal-lography is introduced, and this section contains all the formulæ and information that are likely to be required. Before proceeding to discuss the actual procedure of X-ray analysis, Dr. Mark inserts a chapter on the essentials of the wave theory of diffraction, leading up to the crystal grating by a discussion of the simpler optical systems. He thus gives the necessary analysis to which he can refer when the question of intensity interpretation has to be discussed later.

The author is now in a position to deal with his main problem, the application of X-rays to the structure of the solid, and he proceeds to do so in a very thorough and systematic manner. So far as it is possible to lay down definite rules of procedure, he does it and reproduces for this purpose, in convenient form, tables differentiating the various space groups. These tables, although not quite free from errors, should reduce the time and labour of obtaining the space group of a crystal to a minimum. This determination of space group, or classification of the crystal as belonging to one of the 230 possible configurations, is now a routine business and should always be possible if suitable material is available. But the details of atomic arrangement are not, as a rule, determined when the space group has been found. The complete solution of the structure involves also a discussion of the intensities of the X-ray reflections. This is a much more difficult problem, but in the section devoted to this question the reader will find an excellent survey of the position as it stands to-day.

It is difficult to think of anything essential which has been omitted. Whether his material is in the

form of a single crystal, a random collection of small crystals, or in that very interesting state in which the crystallites are not oriented at random but have some direction in common, the worker will find here the necessary information to enable him to attack his problem No attempt has been made to gloss over the difficulties, but, in spite of this, the book is essentially a practical one Some of those to whom it is especially addressed may find it difficult in places, but they can rest assured that they are not likely to find a simpler yet equally comprehensive account elsewhere. The occasional excursions into mathematics need not deter them unduly. They will find that the working rules are often independent of this analysis and quite intelligible even if all the steps leading to their deduction have not been followed in detail.

Here, then, is a book especially for the practical worker, a book which he will keep on his desk and to which he will find himself continually referring. Every one whose interest lies in this field owes Dr. Mark a debt of gratitude for his labours in writing such a sound and such an eminently useful work, and there will be many among them who would appreciate the appearance of an English translation We have but one quarrel with it, in due course and that is its price. It is certainly a large volume, and the many excellent illustrations and tables must have increased the cost of production, but it seems a pity that a book which is invaluable to all concerned should be issued at a price which puts it almost beyond the modest purses of many to whom it would be most helpful.

## Primitive Peoples of Assam.

The Ao Nagas. By J. P. Mills. With a Foreword by Henry Balfour and Supplementary Notes and Bibliography by Dr. J. H. Hutton. (Published by direction of the Government of Assam.) Pp. xviii + 500 + 32 plates. (London: Macmillan and Co., Ltd., 1926.) 30s. net.

THE Government of Assam is evidently not content with that superficial knowledge of the decaying culture of its subjects which is so frequent a failing of governments which have to deal with primitives; for the present volume, published under Government auspices, is an addition to an important series of monographs on the more primitive peoples of Assam and maintains the high standard of the earlier volumes. Mr. Mills gives us the results of an intensive study of one important group (comprising a population of some 30,000) of the peoples of the Naga Hills.

Material culture, social organisation, and religion are exhaustively dealt with, and a short grammar of the language is given.

It is interesting to find that the clans in most of the Ao territory are grouped into three exogamous phratries, an unusual form of organisation, while in one part there is a 'dual organisation' such as we find in parts of Melanesia. It has not escaped Mr Mills's notice that Melanesian affinities are very numerous, and his book affords further proof of the close cultural connexion between the two areas A feature of the social organisation, worthy of special remark, is the grouping into three-year agegrades, a grouping not brought about by mitiation but directly dependent on the year in which a person is born. Grades within the 'men's house' result from this arrangement, and even the elected councillors of the village form a wider age-grade of a generation, the older generation of councillors being eventually replaced en bloc by the next generation below.

The Ao believes that he has a number of souls, one of which is, perhaps, better regarded as 'soulsubstance,' though Mr. Mills does not use this term. Head-hunting, a most important institution of the Nagas, is closely connected with these beliefs, for the souls of dead men are wanted to fertilise all vegetable and animal life and to add to the general stock of vital essence in the village, and the soul is located in the head above all other Sacrifices to stones and spirits are most important, and there is a complex series of feasts with sacrifices by means of which a man acquires merit. Some interesting notes on the effects of mission work are given in an appendix, and Mr. Mills ! reaches the conclusion, favoured by most anthropologists, that, although the mission may confer ; considerable good on the native, much harm is also done by the destruction of tribal life beyond the point of political necessity.

The usefulness of the book is augmented by a chronological bibliography of the Naga Hills by Mr. Hutton, who has also added valuable notes to the text. The book is well illustrated and provided with a map. There is an excellent index.

Mr. Mills is to be congratulated on his valuable contribution to ethnology, for, as Mr. Balfour remarks in the foreword to the work, "detailed ethnographical monographs, such as the present work, compiled without the bias of any fixed and inelastic theory, afford to the comparative ethnologist reliable material upon which he can work," and, it may be added, such monographs are comparatively rare.

W. E. Armstrong.

## Science and Survival.

The Bridge: a Case for Survival. Compiled by Nea Walker With a Prologue and an Epilogue by Sir Oliver Lodge Pp xi+314+16 plates. (London, Toronto, Melbourne and Sydney Cassell and Co, Ltd., 1927.) 21s. net.

SERIOUS study of the phenomena of the 'mediumistic' trance can be divided into two main classes—the work hitherto done through mediums on supposed supernormal communications which are alleged to come from the dead; and the elucidation of those products of automatism usually styled the 'cross correspondences.' Of these, the flist class is of some considerable scientific interest, and the present volume is a further contribution to the subject along those lines

A devoted married couple, Mr and Mrs White. were separated by the death of the former, and the latter, seeking consolation, applied to Sir Oliver Lodge for assistance As is usual in such cases. the applicant was put in touch with Sir Oliver's secretary, Miss Nea Walker, the compiler of the present volume. With her help Mrs White visited certain mediums in Cardiff near her home, and with them she obtained information which. it is alleged, they could not have normally known This beginning was supplemented by sittings on behalf of Mrs White taken by Miss Walker with the medium Mrs Leonard, and also by private sittings with Miss Walker's sister, Damaris, who is supposed also to possess 'psychie' faculties Later, Mrs. White herself had sittings with Mrs. Leonard, and finally dying she 'came through' at sittings which Miss Nea Walker arranged with Mrs. Leonard. This is, in short, what is known as the White Case, and it is here presented as evidence for the survival of bodily death and the continued interest in, and knowledge of, earth conditions by those who have passed beyond the veil.

The evidence consists in the main of a mass of intimate and trivial information recognised as appropriate by Mrs. White, and in many cases given through mediums and to sitters unknown to her or to her deceased husband. Such trivialities do not weaken the evidence. In certain cases they strengthen it, especially when the material is of such a nature as not to lend itself easily to coincidence. Thus, at one sitting when Miss Walker was acting as deputy for Mrs. White, the 'communicator,' purporting to be Mr. White, remarks that he thinks that at the end of the previous week, about nine days ago, they were looking at a sunset together. As a matter of fact, exactly nine

days previously, Mrs White had noted down in her diary that she had been looking at a sunset and had been thinking of her life with her husband whilst doing so. There are a good many incidents of a similar character scattered up and down the records of the sittings, and interspersed among them are names of persons connected with Mrs. White which would not have been easy to obtain through normal means

Now it would be hazardous to advance the supposition that all the information given through the various mediums and here described was derived from normal sources revealed fraudulently. Certainly it would seem that at least some of it was derived from some hitherto unrecognised source which is usually described as 'supernormal' However that may be, it is a pity that some competent psychologist, alive to possible sources of error, did not supervise and systematise the experiments from the start Thus, we are told that Miss Walker originally sent Mrs White's letter asking for assistance to "a man in Cardiff" Is it not legitimate to ask who this man was, whether he knew of the mediums to whom Mrs White afterwards went, whether he showed the letter to any one, and if so, whether these persons knew the mediums concerned ? These and many more similar questions immediately arise, but no answer to them will be found in the pages of this book. Again, how unsatisfactory it is to have one of the principal mediums, Damaris Walker, living in the same house with the principal investigator Moreover, what an opportunity was missed when Mrs. White herself died. Instead of sending someone who was not aware of Mrs. White's death to take a sitting for Mr. White to 'communicate,' Miss Nea Walker herself goes, and, presupposing some telepathic rapport between herself and the medium, it is not surprising that Mr White affirms the presence of his wife, although strangely enough the control, Feda, does not seem aware of it.

To any one acquainted with the history of the evolution of the human mind and not already persuaded, "The Bridge" will scarcely carry conviction. It may stimulate independent investigation of the problems underlying the real meaning of the odd phenomena associated with the mediumistic trance. Systematic experiments, independently checked and verified at every stage, are, it is admitted, very difficult of execution, but certainly ought to be attempted. Thus, it ought not to be permitted, as was done in the present case, for the sitter to be present alone with the medium and take personal notes in long-

hand. It is admitted in the 'White Case' that a selection has been made, and it is obvious in what direction it operated. If telepathy occur at all, then the laws underlying it will only be discovered through the most rigid control conditions being applied.

At present we see little appreciation of this fact in the writings of psychical researchers. It remains to be seen whether, when sufficiently strict control conditions are applied, the 'phenomena' tend to disappear as seems to be the case with the so-called physical phenomena of spiritualism When normal knowledge, chance coincidence, common associations, deliberate fraud, and hyperæsthesia are eliminated, what remains ? Is there, in fact, any residue left for examination? Certainly in such 'phenomena' as are exhibited in the published 'cross correspondences' there would appear to be little, if any. In the communications given through mediums there would seem to be something for which no normal explanation is readily available, and this volume provides a good example of the latter category.

## Indian Malarial Research.

Malaria: its Investigation and Control; with special reference to Indian Conditions. By Major Robert Knowles and Ronald Senior-White Pp. vii + 220 + 6 plates. (Calcutta and Simla Thacker, Spink and Co., 1927.) 78 rupees.

HEN the professor of zoology in the Calcutta School of Tropical Medicine, and a worker in the Central Malaria Bureau of the Government of India with previous wide field experience in Ceylon and India, collaborate in a monograph on the investigation and control of malaria intended for men of the Indian assistant-surgeon class, its scientific and practical hygienic value are assured, when they dedicate it with respectful homage to the wives of research workers, in recognition of their sufferings in the cause of science, the illumination of humour helps perspective; and when they permit in the book the issue of advertisements of material pertinent to the subject, they perhaps but follow closely in the footsteps of the School's distinguished founder, for it was he who persuaded the merchants of Calcutta to contribute so liberally, and, so far as they were concerned, so unexpectedly, to its finances that they assured him that his missed vocation was that of company

The first two chapters of the book deal with the malaria parasites in man and anopheles and No. 3026, Vol. 120]

acknowledge fully the writer's indebtedness to Wenyon's "Protozoology," although Knowles is in error in attributing to that book and author the original intimation that if Plasmodium ovale Stephens be valid species its valid name is P. minutum Emin, 1914. That effect of the working of the Code of Zoological Nomenclature was indeed pointed out in the Tropical Diseases Bulletin three vears earlier. While on this subject, it may be noted that the specific names of the anopheles cited do not all appear to comply with the law of These chapters contain three valuable coloured plates of the various stages of development of the three species of Plasmodium parasiting the blood of man, and a fourth, particularly striking in its simplicity and clearness, of the relations of the human and anopheline cycles of the plasmodial life-history

There is one point on which Knowles lays some stress, the statement that gametocytes do not appear early in an infection, not perhaps for ten days or more, their appearance being due, it is suggested, to conditions becoming unsatisfactory for schizogonic multiplication. Warrington Yorke and Maefie, in their transmissions of P vivax by mosquitoes in the treatment of general paralysis, have, though rarely, found gametocytes in the circulating blood as soon as any forms have been discovered there, and, in all instances, two or three days later. It is reasonable to conclude that gametocytes come into existence as soon as do schizogonic forms, but in numbers too sparse to be detected in the circulating blood by our present diagnostic means.

The reasonableness of this explanation is strikingly illustrated by an incident cited in the book where some fifty thin smears from one man were distributed among the School class with the view of eliminating *P. falciparum* infection, for it was intended to use this blood, which was infected with *P. vivax*, in the treatment of general paralysis. Rings suspicious of subtertian malaria were found in three smears, and a crescent in a fourth—Should the sexual forms, essential for the survival of the species, appear only when conditions are unfavourable for schizogonic multiplication, the observation would have wide zoological implications, so that hesitation in accepting this position is justified.

With experience of the diagnostic uncertainty of thin films, such as has just been indicated, there is little wonder that Knowles is a convinced advocate of the thick film for the diagnosis of malaria, and full and careful directions are given for its preparation with a view of ensuring that plasmodia shall always be detected therein if they are present Culture is advocated for diagnosis if the thick film prove negative and doubt still remains, thus following Sinton, in whose hands it has in these conditions been successful, the amount of blood usable amount to 1 c.cm. A fifth coloured plate illustrates the normal and abnormal cells which may be found in a stained blood film.

Very convincingly, Knowles unfolds the argument against 'parthenogenesis' in Plasmodium, but, unfortunately, it is not, as he writes, "now as dead as mutton", it has recently been sponsored by a great French scientific society in considered advice to the French Government.

The line of treatment inclined to is Sinton's alkalme quinine mixture, but as regards total dosage sufficient stress seems scarcely to be laid on the difference in reaction to the cinchona alkaloids which is shown by a recent and by an 'established' infection, both conveyed by the mosquito. Perhaps for the book's purpose such stress is useless, in view of the unlikelihood of detecting a new early infection in those who have been infected in, and have relapsed or been reinfected since, The cinchona alkaloids other than childhood quinine, and the mixture known as cinchona febrifuge, are considered. The very strong reasons against giving quinine by the intra-muscular route are fairly marshalled, the invariably resulting necrosis is stressed, and some of the appalling consequences illustrated After all, seeing that the Indian sub-assistant surgeon does give intravenous injections of tartar emetic for kala-azar at the rate of about two a minute in Assam, there is little excuse by any one to avoid the sure and rapid intravenous route for quinine, where the oral route is contraindicated.

Senior-White describes the making of a malarial survey, and the design, construction, and maintenance of anti-malarial measures, and furnishes appendices. These comprise the breeding places and distribution of Indian anopheles, and a key for the identification of the imagines sponding key for the mature larvæ is accompanied by a sketch of the entire larva with its anatomical parts named; an idea which will, no doubt, be extended to the imago in another edition keys are usefully illustrated throughout. The last appendix consists of a copy of the specification which has been found so valuable for the construction of subsoil underdrains in the Federated Malay States A considerable bibliography follows. The book fills well the limited function for which it is CLAYTON LANE

#### Our Bookshelf.

Comets and the Sun · New Theories regarding their Structure By Dr John W. Weir Pp xvi+72 (London: Longmans, Green and Co, Ltd, 1927) 12s 6d net.

This book is very well illustrated, it contains reproductions of photographs and drawings of Halley's and other comets, made at the principal observatories, also photographs of sunspots and the corona, and a large coloured drawing of a solar prominence. A considerable part of the text is taken up with quotations from the writings of well-known astronomers, some of the passages quoted were, however, written before the recent advances in atomic physics, and are now somewhat out-of-date.

Cometary physics are very difficult to explain in a perfectly satisfactory manner, and it is unwise to be too dogmatic in condemning any suggestion as being certainly unsound, some of the author's suggestions are, however, rather difficult to accept Thus he suggests that the tails of comets are bounded by an envelope, which he appears to picture as a sort of membrane It must be admitted that the well-known drawing by Gen G. H Willis of the great comet of 1882 lends some support to the suggestion, yet it is difficult to reconcile it with our knowledge that the tail is not at rest with respect to the head, but is continually being driven outward by powerful forces. Again, the author invokes currents in the interplanetary medium to explain some features of the tail. The study of cometary movements clearly shows that the medium offers no sensible retardation to the motion of the comet as a whole; still less could its differential action between different parts of the comet be sensible. There are similar difficulties in some other suggestions, still we may admire the author's enthusiasm for his subject, and his desire to throw new light upon it, even if we are unable to A. C. D. C. accept all his ideas

A Text-Book of Geology By Philip Lake and R H. Rastall. Fourth edition. Pp xiv + 520 + 33 plates (London . Edward Arnold and Co., 1927) 21s net

THE fourth edition of the deservedly popular "Lake and Rastall" remains unaltered in plan, but a considerable number of minor changes and a few brief additions have been made. For the most part these are insufficient to indicate to the student the remarkable developments in geological interpretations that are at present in full swing. It may be that the authors feel that the time is not yet ripe for the incorporation of modern advances into the scheme of an elementary text Certainly it would be difficult to introduce the newer outlook into any already existing text-book Nevertheless, more attention might have been given to isostasy; the structure of the crust as revealed by earthquake records; the work of the Carnegie Institution of Washington on the nature of volcanic activity, and the far-reaching consequences of the recognition of radioactivity as a source of internal energy Only nine lines are devoted to the continental drift hypothesis, and vulcanicity in all its forms is still regarded as "merely a secondary effect of the greater class of phenomena dependent on the cooling and contraction of the globe as a whole"

At present there is generally a marked difference between geological text-books and courses of lectures, and the above comments are offered in the hope that in future editions of this and other books of similar scope (e.g. American) some serious attempt will be made to make the gap less obvious Meanwhile our "Lake and Rastall" remains by far the most generally useful text which is at present available for elementary students. We welcome its improvements and hope for more when the present edition is exhausted.

La construction collective de la maison en Kabylie: étude sur la coopération économique chez les Berbères du Djurjura. Par Prof. René Maunier (Université de Paris Travaux et Mémoires de l'Institut d'Ethnologie, Tome 3) Pp in +81 +3 planches (Paris Institut d'Ethnologie, 1927.) 45 francs.

In this study of the erection of a Kabyle house the author is primarily concerned with the sociological aspect, and the technological and religious aspects —for certain stages of erection involve a religious ritual with sacrifice—are dealt with only summarily and incidentally in so far as some account of them is necessary to comprehension of its building as a social activity. The character of the Kabyle house is determined to a large extent by the environment and by the economic activities of the people intensive character of the occupations of the people, as is usual in the circumstances, tends to the concentration of a completely self-supporting unit under each roof Each house is inhabited by a single family. It is, however, essentially the place of women's occupations; the men use it only for eating and sleeping, while unmarried sons of adult age sleep in a kind of club-house. But as a small group of this kind is not adequate to the labour of erecting a new house, the help of relatives and then of the whole community is called in. New houses are usually erected on the marriage of a son, and there is a tendency for each new house to be grouped around that of the parents, thus creating a community within a larger unit. M. Maunier's book is a valuable piece of work which well illustrates the function of and method of working of a communal activity.

The Story of Myths: for the Use of Students in Training Colleges, and Others. By E. E. Kellett. Pp. v+275. (London: Kegan Paul and Co, Ltd, 1927.) 7s. 6d net.

In the course of the lectures, or rather informal talks to training college students, which furnished the material from which this book has been made, the author disclaims any attempt at exhaustive treatment of the various classes of myth. He has, however, covered a sufficiently wide field, and within the limits he has imposed upon himself, his

treatment of the subject is scholarly and shows The chapters on psychological elements in the growth of myth and on existing relies of old custom and myth will be found especially valuable in giving the student the point of view of the student of folklore in approaching his material, and the conditions, both psychological and cultural, of the myth-making stage m the development of the human mind. The principal classes of myth which the author analyses are those relating to the heavenly bodies, sky and sea, creation, great catastrophes such as the flood, birth and death, and twins The chapter on the history of folklore might have been a little more systematic. Some notable names are not mentioned, for example, Sir Laurence Gomme and Sir John Rhys. A select bibliography would have been an advantage, and have added materially to the value of what is, within its limits, an excellent The index is particularly good and useful

Applied X-rays By Prof. George L. Clark. Pp xiii+255. (New York · McGraw-Hill Book Co., Inc; London McGraw-Hill Publishing Co., Ltd, 1927.) 20s net.

In this admirable volume, Prof. Clark gives what is probably the first extensive and scientific account of the progress made in the application of X-rays to the solution of the special problems of industry. Even to readers more or less in touch with X-ray work in general, the extent and variety of the subjects dealt with in the book will come as a surprise The application of X-rays to the solution of problems connected with the behaviour of metals and alloys under strains, with the composition of chemical compounds, with catalysts, colloids, textile fibres, varnishes, dyes, soaps, dielectries, adhesives, abrasives, cements, coal, and gems, are some of the many subjects with which the author deals. It is not surprising that he foresees a great future for this new and rapidly growing branch of applied science.

Prof. Clark writes not only with enthusiasm but also with knowledge and judgment, and has succeeded in condensing into small compass a considerable amount of information, much of which is drawn from sources not too easily available in Great Britam. The book is excellently written, well illustrated, and charmingly produced. We congratulate the author on having so admirably filled a real gap in our current scientific literature.

The Theory of Strong Electrolytes: a General Discussion held by the Faraday Society, April 1927. Pp iii + 333-544 (London The Faraday Society, 1927.) 15s. 6d. net.

The Faraday Society's general discussion on "The Theory of Strong Electrolytes," held at Oxford on April 22 and 23, 1927, was noted somewhat fully in these columns (May 7, p. 676). A full report, containing the original papers and the discussion upon them, has now appeared, and will be welcomed as a work of first-class importance on one of the most controversial aspects of physical chemistry.

### The Origin of the Nebulium Spectrum.

The identification by MM  $\,$  F. Croze and C  $\,$ Mihul of a number of intercombinations between quartet and doublet terms of O II (C R, vol 185, p. 702), which has been announced since my letter of last week was written, provides important data for the further consideration of Mi Bowen's suggestion as to the origins of certain lines in the spectra of gaseous nebulæ

Bowen's values for the quartet terms of O II were based upon a sequence of three  $^1P$  terms, and it was understood that while these were relatively correct among themselves, they were not necessarily quite correct with respect to the previously determined doublet terms. The discovery of intercombinations, however, leads to a correct relation between the two sets of terms. Without going into details, it may be stated that while Bowen's estimate for the  $^4S_2$  term was 283366 (*Phys Rev.*, vol 29, p. 243), the new data indicate a value of 283028, within limits of error depending upon the measurement of lines in the extreme ultra-violet. Thus, adopting Bowen's interpretation of the nebular lines  $\lambda 3728, \lambda 3726$ , we have

The mean value of  ${}^4S_2 = 283020$ , is in remarkable agreement with  ${}^4S_2 = 283028$ , as determined entirely from laboratory spectra, involving lines in the extreme ultra-violet. Taken in conjunction with the evidence in favour of similar irregular combinations of terms of N II and O III, this result leaves little doubt that Bowen's interpretation of some of the chief nebular lines is correct.

Since the ordinary combinations which build up the laboratory spectra of O II, O III, and N II do not occur in nebulæ, it would appear that the conditions in nebulæ which facilitate the occurrence of irregular combinations of deep spectroscopic terms are such as to prohibit the regular combinations which produce the familiar laboratory spectra of the same elements.

I should like to take the opportunity of making a small correction to my letter. In the paragraph on p. 582 in Nature of Oct. 22, beginning with "Bowen's assignment of the strong nebular lines  $\lambda 3728.91$  and  $\lambda 3726.16$  to O II leads to term values for  $^2D_{32}$  of the expected order of magnitude, and the consequent calculation of the red line  $\lambda 7325...$ ",  $^4S_2$  should have been substituted for  $^2D_{32}$ , and the word 'consequent' should have been omitted A. FOWLER.

Imperial College of Science, South Kensington, Oct. 19.

#### Absorption Bands of Ergosterol and Vitamin D.

WE have recently shown (Jour. Chem. Soc., 1927, p. 2000) that as the reaction

ergosterol 
$$\xrightarrow{\text{u.v. light}}$$
 vitamin D

proceeds, the characteristic selective absorption of ergosterol in the region 260-320  $\mu\mu$  diminishes in

No. 3026, Vol. 120]

intensity at a uniform rate. At the same time a new selective absorption in the region 230-270  $\mu\mu$ , with a maximum at 247  $\mu\mu$ , gradually makes its appearance, and under our experimental conditions of concentration and light intensity the band is most clearly defined (that is, shows the maximum persistence) after 120-150 minutes' irradiation. Further irradiation now brings about the gradual disappearance of the band at 247  $\mu\mu$ . Animal experiments have indicated that preparations exhibiting this band show great antirachtic potency, whereas the over-irradiated samples are much less active.

As a necessary consequence of these results it follows. (a) that anything approaching a satisfactory yield of vitamin D requires prolonged irradiation, because the pro-vitamin bands disappear slowly, and (b) that the mercury vapour lamp is unsuitable for this particular photo-chemical reaction because it emits radiations capable of decomposing the product (vitamin D) Our assumption that the band at 247  $\mu\mu$  is due to vitamin D provides an explanation for the well-known instability of the vitamin to light, and unless this assumption is made, not only is the meaning of the band unknown, but we are also left without any physical mechanism for the photochemical decomposition of the vitamin

The absorption bands of ergosterol and vitamin D overlap to some extent in the region 230-270  $\mu\mu$ , so that the two substances will compete for these radiations. With a high concentration of ergosterol most of the energy at these wave-lengths will tend to form vitamin D rather than to decompose it, that is, the reactant will act as a screening agent hindering the secondary decomposition of the resultant. It is inevitable that the concentration of vitamin should rise to a maximum and ultimately fall to zero as the time of irradiation is prolonged, the exact value of the maximum depending on the initial concentration of sterol and the spectral distribution of intensity in the light source. We suggested that in order to obtain a high yield of vitamin, only rays longer than  $270 \mu\mu$  should be used, and m order to do so we stated that either the light from the mercury vapour lamp must be screened, or an alternate source used.

The conclusions (a) and (b) have been severely criticised by Messrs. Rosenheim and Webster (Lancet, Sept. 17, 1927) as not being in agreement with the results of their animal experiments. Indeed, these authors express the fear that their results involve the necessity for rejecting the 247  $\mu\mu$  band as a property of vitamin D, and they also issue a warning against the too-ready acceptance of conclusions based on spectrographic analysis. We are of the opinion, however, that our work supports in a most striking manner the results arrived at by them, and that these were indeed foreshadowed by the spectroscopic evidence. They find that under their conditions of irradiation a maximum antirachitic potency is reached after 30 minutes, this potency then remaining fairly constant for a further 210 minutes. By a roughly quantitative method they show, however, that at the end of half an hour only ten per cent. of the ergosterol has been removed, so that the maximum amount of vitamin D present at any time cannot exceed this figure. Actually, the quantity would almost certainly be less, since some must inevitably have been further changed into mactive material. How much this may be is unknown, as up to the present no quantitative relationship exists between vitamin D and antirachitic potency. Neither the animal nor the spectroscopic test is as yet able to express vitamin D in more than relative terms. Although we are wholly ignorant of the nature of the chemical change which occurs when vitamin D is formed (i.e whether the maximum yield could be 100 per cent. or only 25 per cent. provided no decomposition occurred), it still remains true that the presence of 90 per cent. of unchanged material is hardly consistent, from a strictly scientific point of view, with its efficient utilisation.

Again, Messrs Rosenheim and Webster find that even after 240 minutes' exposure, 10 per cent of ergosterol still remains in the irradiated mixture. Such a result is in complete accord with our observations that prolonged irradiation is actually necessary for the complete conversion of the ergosterol, irrespective of the ultimate fate of the vitamin. These spective of the ultimate fate of the vitamin. authors seem to have completely mistaken our contentions regarding the employment of the quartz mercury lamp. The spectroscope rendered it perfectly clear that vitamin D was formed from ergosterol by use of We would, however, the mercury vapour lamp again emphasise that as long as the light source contains radiations between 230-270  $\mu\mu$ , photodecomposition of the vitamin must ensue, and this will become the more rapid the more the screening effects of the original ergosterol is lost by its conversion into the vitamin

Mr. A. E Gillam, working with one of us (R.A.M.), has been studying the actinometric control of the irradiation process. Using the same concentration as was studied by Rosenheim and Webster, it was found that the persistence of the 247  $\mu\mu$  band remained constant over a long period. It has also been found that irradiation behind vitaglass screens does not effect the expected increase in vitamin concentration. While these results do nothing to weaken the argument for the validity of the correlation between the 247  $\mu\mu$  band and the vitamin, it must be concluded that there is still ample reason to justify us in pursuing the study of the irradiation process by spectrographic means. Finally, we would emphasise that our argument, which is based solely on the disappearance of the pro-vitamin D bands, is not affected if it be eventually shown that these are not due to ergosterol but to some constituent contained therein.

## Barrier Reefs of Tahiti and Moorea.

To answer completely the letter from Prof. Davis, published in Nature of Sept. 3, would take too much space, so, as he suggests, I leave my papers to speak for themselves when they appear. To explain the presence of basaltic stones on the 'barrier' reef by a filling in of the lagoon, and its re-excavation, is really a special pleading against the simpler hypothesis of a once continuous reef; I can myself suggest a much simpler alternative, namely, by their being floated across entangled in the roots of trees, floated out to sea by floods. I reject this means of transport, however, because the stones are invariably rounded, which could only be the case when the tree has been uprooted from an alluvial flat. The reefs and their embedded stones are certainly pre-glacial, when such flats were of small extent, especially if, as Prof. Davis holds, the valley mouths were drowned, and the stones, in the great majority of cases, could have been only angular fragments of the rocky sides of torrents.

I can assure Prof. Davis that the geological aspect in general, and his own work in particular, are fully recognised by all workers who, like myself, have been so greatly influenced by Prof. J. Stanley Gardiner, and his forthcoming book will be read with the greatest interest. At the same time biologists cannot agree that their contribution has been, or will ever

be, "the less significant side" of the problem, and I suspect that Prof Davis did not quite intend this meaning; the geological aspect is fundamental, but alone it is as dead as 'faith without works'. The mention of such names as Gardiner and Mayor is sufficient to prove the value of biology, but, as the present discussion is on the reefs of the eastern Pacific, it may be more interesting to take new, and as yet unpublished, examples from that region

The Marquesas have been the subject of much geological theory, but it was reserved for a biologist to find that the absence of reets from that group is a matter of coral ecology after all The foundation, growth, and recession of reefs cannot be completely understood without even more knowledge of the life of corals than we have at present. This subject is only at its beginning These basaltic stones scattered upon, and bedded into, the Tahitian "barrier" could never have been seen by a geologist, and I think their discovery may be a by-product of the long hours I spent during seventeen years inspecting pearl beds in the Red Sea Also the fact of the recession of these reefs is as interesting to the geologist as to the biologist, but it can safely be said that it would never have been discovered by the former. The importance of the origin of surf-resisting reefs, as distinguished from mere loose heaps of coral, has been insisted upon by Prof. Davis himself. This is decidedly a biological problem, depending upon the interaction of the stony seaweeds and other organisms with coral, as described by Gardiner, and it is also illustrated by the rejuvenated portions of the Tahitian reef edge.

Prof. Davis explains the occurrence of high cliffs on the north side of Moorea Island by a local delay in reef building through the outwash of alluvium from the two fjords of this coast. As he states, this alluvium would be carried westwards, and it would therefore affect only the western two-thirds of the coast, and the reefs would be markedly narrower westwards than they are to the cast, which is not the case. The uniformity of the width of the reefs is one of the curious features of the whole group, and those of Moorea well exemplify this. In my account of the Island I have taken the view that the straight north coast is faulted, the two fjord-like bays are due to explosions, while the south coast has tilted downwards and drowned its valleys. All this occurred early in the island's history and has had no effect upon the form of its reefs. I have no wish to make this a general statement, applicable to any other island.

general statement, applicable to any other island.

Agassiz gives no detail of his dredging in the Tahitian lagoons, and I have good reason for distrusting his general statements. My own dredgings . have been far too few, but the most enclosed of all the lagoons, from Papeete round the north-west quadrant of the island to Taapuna Pass, was thoroughly explored by dredge. Its sand is surprisingly uniform in character, angular and fairly coarse, and contains only 15 per cent. of non-calcareous matter. absence of the red mud, which is poured in at every heavy rain, is remarkable. I conclude that this lagoon is filling in, but much more slowly than I, for one, expected. Proof is wanting of what is happening at the bottoms of those lagoons of Tahiti which are certainly being excavated for the first few fathoms of their sides, and I hope to obtain it by a series of dredgings on my next visit. If at the same time some mexpensive borings could be taken (1) in the valley flats, (2) at the bases of the marine cliffs, (3) in the reefs, we should not be dependent upon inference for the discussion of the points raised by Prof. Davis, and by my own work. I do not reject the evidence for subsidence given by the valley flats, but pending positive information, they are as well

accounted for by lateral cutting of their streams as by the infilling of bays. Flat-bottomed valleys abound wherever a stream's load of alluvium is excessive, conspicuously, eg., among the mountains of the Red Sea Finally, I see no reason why subsidence should convert a fringing into a barrier reef, but, in Tahiti, see evidence that drowning would tend the other way, to the production of a wide flat.

CYRIL CROSSLAND.

The Zoological Laboratory. Cambridge, Sept. 2.

#### Earthquake Warnings.

In a letter in Nature of Oct. 13, 1923 (p. 538), I proposed a possible method of obtaining warnings of the occurrence of earthquakes. "It seems probable," I wrote, "that the rupture, whatever its nature may be, that gives rise to the actual vibratory shock of an earthquake is preceded by a strain or distortion of the earth's crust, which gradually increases till the stress that causes it is suddenly released. The existence of this strain should be evidenced by a progressive sag or tilt of the surface" I suggested that a new form of the Milne-Shaw seismometer, which has a fixed mirror, as well as the mirror attached to the pendulum, might be employed for detecting such a tilt, and that, "if it be found that shocks are in fact heralded by a definite tilt, it may be possible to arrange for an electric bell to attract the attention of the observer when such a tilt occurs. If he is satisfied that there is sufficient evidence of an approaching earthquake, a general alarm can be sounded."

At the meeting of the Geodetic and Geophysical Union at Prague in September, I had the good fortune to meet Dr. Akıtune Imamura, professor of seismology at the Tokyo Imperial University, and to learn from him that in Japan earthquakes have in fact been preceded by such tilting as I had suggested In his report to the Union (printed in Paris in the present year) he tells us (p. 7) that the Tango earthquake of Mar. 7, 1927, was indicated by an upheaval a metre at a maximum at Mitu and Sunakata, ie. along the coast in the east of the Gomura fault, attaining this state two and a half hours before the great shock took place, although the change was less pronounced on both sides of those places.

Similar phenomena were observed on the occasion of previous destructive earthquakes on the coast of the Sea of Japan. Prof. Imamura gives a table showing an upheaval before the shock in five earthquakes between 1793 and 1927. The maximum temporary elevation varied from one to two metres and preceded the actual earthquake by from half an hour to five hours. He concludes "that the assumption that topographical change precedes earthquake" (Dr. Imamura's italics)

may not be so absurd.

"Ishimoto's clinograph, which can register a tilting as small as a decimal of a second, registered at Tokyo a characteristic tilting which appeared from a few weeks before, to the day of the great Tango earthquake. Similar phenomena were observed with his instrument installed at Mıyadu, in the case of the shock on Apr. 1, the biggest of the after-shocks of the Tango earthquake."

"The Earthquake Research Institute of the Tokyo Imperial University is attempting to have, among others, a network of stations, each equipped with a pair of clinographs and other auxiliary instruments necessary for carrying on the study concerning the

earthquake prediction.

I am not aware that my suggestion has been acted on anywhere else.

It would seem desirable that, in regions subject to serious earthquakes, a number of local stations should each be equipped with a pair of simple horizontal pendulums, so adjusted that if any unusual tilt occurs a bell should ring automatically in the office of a central observer and the locality indicated there by He would then judge from the number of stations affected, and the record of his own seismometer, whether the indications were sufficient to wairant him in giving the alarm.

I may add that I am informed by Sir Gilbert

Walker that a slight tilt has sometimes been observed in the seismographic records of Simla setting in a few minutes before the vibrations from an earth-

quake with a comparatively near epicentre.

In conclusion, I should like to point out that the earthquake warnings to which I have been referring are quite distinct from long-period earthquake predictions based on observation of the secular relative movement of adjoining masses of the earth's crust. Such movement results in a stress in the tract intervening between them. When this stress exceeds the limit of elasticity of the rock, rupture will take place followed by an earthquake shock (H. F. Reid, Beitrage Geoph., vol. 10, pp. 328-345; 1910; J.W Evans, Q.J.G.S., vol. 66, p. 346; 1910). From such observations it may be possible to form some idea when the limit will be exceeded, and thus to predict the occurrence of an earthquake with an error of, perhaps, not more than, say, half-a-dozen years The actual disruption of materials under stress is, however, as is well known, immediately preceded by increased deformation, and it is the tilt that results from this that provides the earthquake warning. The interval between the commencement of the warning tilt and the shock is usually brief, but in most cases it will be long enough to enable loss of life to be largely, if not entirely, prevented.

The same report contains interesting details of the horizontal and vertical movements accompanying the earthquakes of 1923 and 1927 respectively. These are clearly shown in the maps and reproductions of photographs that accompany it.

JOHN W EVANS.

Athenæum Club, London, Pall Mall, S.W.I.

### The Consistence of Mixtures of True Fluid and of a Fluid with Solid Particles.

When two fluids which have no chemical action on one another and are mutually insoluble, are well shaken together, the mixture consists of small globules of one fluid embedded in a matrix of the other, and is in general less fluid than either of the constituents taken separately. Common examples of this sort of stiffening are to be found in cream, mayonnaise sauce, and butter (mixtures of oil and watery fluid), but the most striking case is that of oil and mercury, which forms a stiff black mud. In the first three examples it is the oil which takes the globular form, and in the last the mercury.

Since the surface tension of oil-water is much less than that of mercury-oil, it would seem that the surface tension difference is not the factor determining which of the two fluids shall persist as globules. This probably depends on the qualities which tend to make fluid films stable The stiffening of these mixtures may be explained by the fact that when they are stirred or distorted, a flow has to take place in the narrow channel separating the globules and that this is resisted by viscosity.

Suppose that a large number of small solid spheres are placed in a vessel, and are so disposed as to occupy

the minimum space (i.e. that each is touched by its neighbours at twelve equidistant points), and that then fluid is added until the spheres are just covered If now the arrangement of the spheres is disturbed in any way, the level of the fluid will fall in consequence of the increase of the volume of the interstical cavities, and the viscous resistance to be overcome is proportional (among other things) to the aggregate surface of spheres-or, in other words, inversely as their diameter.

When the spheres are globules of liquid, distortion of the mass will also cause a deformation of the individual globules, and this will be resisted by an elastic reaction due to the internal pressure, which exists in them by virtue of surface tension. The internal pressure in a globule of diameter D where the surface tension constant is T is equal to T/D, and this becomes considerable when D is small a mercury-m-oil globule, for example, if D is 1/2000 in the pressure will exceed 40 lb per square inch—about as much as the pressure in an ordinary bicycle tyre, but in a collection of such globules, if deformed, the internal pressure may be much greater, for the deformation tends to make the globules into dodecagons, and the pressure is inversely proportional to the least radius of curvature of the deformed sphere. (In such fats as butter, in which the oil solidifies at low temperature, additional viscous resistance is offered to deformation.)

It would be a waste of space to go fully into the quantitative (and fairly simple) relations between volume of the interstices as the arrangement of the globules departs from the minimum volume pattern, but the results may be shortly stated thus:

(1) In a collection of fluid globules closely embedded in a second fluid, resistance is offered to deformation by a force which is partly elastic and partly viscous, the viscous force being much the more important.

(2) The resistance increases as the diameter of the

globules diminishes.

(3) When the globules are closely packed any deformation of the mixture involves an increase of volume, not, of course, of the globules, but of the

spaces between them

The expansion of mixtures from this cause is well shown in such material as glazier's putty (oil and chalk). Putty when well kneaded is soft, and if rolled into a cylinder can be easily lengthened or shortened for a certain distance by applying force to the ends. If, however, the alteration of length exceeds a definite limit, the resistance increases very rapidly, as if the motion were opposed by a mechanical stop. At the same time, the appearance of the surface suddenly changes, losing its shiny gloss and becoming dull and 'matt.' This happens when the particles of chalk, which at first were separated by oil, have been brought into contact, and further distortion withdraws the oil from the surface to fill the enlarged internal cavities. The same explanation applies to the dry patches which (as most people must have observed) appear for a short time round footsteps on wet sand recently left by the tide. Most people also must have noticed that by tapping on the sand with the foot, the surrounding area becomes wet and softa quicksand in fact—thus showing that the sand particles are separated by fluid, but the wet area quickly resumes the dry appearance when a steady pressure is applied.

Many superstitions have collected about the character of real quicksands, and it would be a matter of interest to examine the conditions under which they are formed.

Exeter.

The Thickness of the Continents.

This important datum, as arrived at on seismic evidence, has been referred to frequently in the pages of Nature Most readers, I think, will agree that the conflicting character of the results is discouraging. Within the last two or three years the average depth of the continental layer has varied from 12 to 60 km.

There is little doubt that the most trustworthy information available is that based upon isostasy. The object of the present letter is to direct attention to an important paper by Alfred Wegener in the current number of Gerlands Beitrage zur Geophysik (Bd. 17, H. 3), which bears directly upon the isostatic method of estimating continental thickness and, as I think, involves a correction upon

all previous calculations based on isostasy.

In the course of a discussion of Gutenberg's conclusion as to the existence of a great depth of sial spread over the Atlantic floor, Wegener points out that the average depth of the ocean should not be taken as defining the surface of the sima but, rather, those soundings which are found to prevail over the greatest areas. The 'Haufigkeits Maximum,' so far as the observations go, defines a depth of about 4700 m, and he considers that further knowledge of ocean depths probably will refer the sima surface to a depth of about 5000 m. The lesser soundings obtained over the ocean are to be ascribed to the presence of more or less sial, which floats in the denser sima. In the Azores such oceanic sial attains the surface. There are considerable areas in the Atlantic floored by such submerged plateaus and islands but, also, great areas floored by sima as indicated by the greater depths. In the Pacific the sial is absent or scarce.

This interpretation of oceanic soundings commends itself as almost certainly correct. We must accept it if we are to remain true to isostasy and profit by the results obtained by Meinez over great ocean areas: results brought before the recent International Union of Geodesy and Geophysics (NATURE, Oct. 1, p. 494).

Wegener's interpretation of the soundings directly affects our application of isostasy to finding the average continental thickness, as he, himself, recog-Thus, some few years ago I sought to estimate continental depth on isostatic grounds. taking the mean depth of the ocean (3.8 km. Murray) as defining the surface of the sima. The thickness came out as 30.7 km. ("The Surface History of the Earth," p. 35). The other data m volved the average density assigned generally to continental materials, that is, that of granite (2.67) and that proper to the substratum, that is, that of basalt (300); it being further assumed that pressures and temperatures prevailing in the depths leave the ratio of these densities unaffected. But in this calculation the average emergence of the continents over the surface of the sima is taken on the prima facie plausible assumption that the mean depth defines the surface of the latter. Correcting the figures m accordance with Wegener's views (as above) the average continental thickness is found to be 37 km.

This result appears to possess the minimum degree of uncertainty. The thermal methods cannot be regarded as sufficiently dependable to over-ride it. For, in fact, it may well be that the radio-activity of the continents diminishes somewhat downwards as itappears to do in the whole depth of the substratum so far as we can ascertain. Such a diminution in radio-activity would probably be attended with some increase in density. But the latter change may be small. Thus if anorthosite, which Daly regards as probably a gravitative differentiate of gabbroid

(basaltic) magma, entered considerably into the basal structure of the continents, the radio-thermal effects would seem to be reduced some fifty per cent. and the density be only slightly affected. If diorites shared in the deeper continental structure (as Holmes has suggested) the same effects would arise, but in

lesser degree.

It would seem that upon the thermal aspects of the question all we can say is that our estimates point clearly and unmistakably to basal temperatures adequate to annul or greatly reduce escape of heat from the underlying sima or, even, possibly to give rise locally to some downward flux. and that as regards surface gradients the data are so uncertain that beyond their testimony to the continued ascent of heat from beneath in amount sufficient to support and confirm our views as to its radioactive origin throughout continental materials of relatively high J. JOLY. radioactivity—we cannot go.

Trinity College, Dublin, Oct 3.

## Dug-out Canoe in Algoa Bay.

MR F W. FITZSIMONS has sent me a fragment of wood from the dug-out canoe washed ashore in Algoa Bay, described by him in NATURE of May 21, and since referred to by other correspondents in these columns. I am naturally far from desirous of entering into the discussion on the exact origin of the canoe, but the results of my examination of the wood show, I think conclusively, that the canoe had its origin somewhere in the Bay of Bengal off the coast of Burma or the Malay Peninsula, and that the Nicobar Islands cannot have furnished the particular timber from which it was made.

Examination of the fragment received from Mr FitzSimons shows that the wood is derived from an Indo-Malayan tree of the family Anacardiaceæ. The anatomical structure, which is quite distinctive, identifies the specimen with one of two closely related genera, Gluta and Melanorrhea. Species of both these genera are distributed throughout Indo-Malaya and are represented in the Mergui Archipelago by Gluta tavoyana Wall. and Melanorrhæa glabra Wall, but so far neither genus has been recorded from the Nicobar Islands. A study of specimens or descriptions of all the genera of the Anacardiaceæ represented in the Nicobar Islands has not revealed any indigenous wood which bears more than a tamily resemblance to the timber of the canoe.

## An Aspect of the Biochemistry of Sugars.

THE ISSUE of NATURE of July 9, p. 44, contains a communication by Prof. R Robinson, in which, on purely speculative grounds, far-reaching conclusions are drawn (1) regarding the origin in Nature of galactose, and (2) regarding the configuration of the pentose of the plant nucleic acid. The second conclusion met with the approval of Haworth.

The views of Prof. Robinson are contradicted by

recorded facts.

(1) Glucose-3-phosphoric acid ferments at the same rate as glucose. Should glucose-3-phosphoric acid on hydrolysis pass into allose, then the rate of fermentation would be lower than that of glucose. Glucose-6-phosphoric acid (very stable ester) ferments at a lower rate than glucose.

(2) In the pentosephosphoric acid of the yeast nucleic acid, the phosphoric acid is attached to carbon atom (5) which is symmetric.

Furthermore, Dr. A. L. Raymond and the writer have found that on hydrolysis of glucose-3-phosphoric acid, only one sugar, namely, glucose, is obtained.

A more detailed analysis of Prof. Robinson's communication will be published in the Journal of Biological Chemistry in connexion with the report on the hydrolysis of glucose-3-phosphoric acid.

#### The Isolation of Protoactinium (Element 91).

THE exact relation of the actinium to the uraniumradium disintegration series has been a matter for discussion since the discovery of actinium. A. S. Russell (NATURE, Sept. 17, p 402) has recently discussed the problem and made a new attempt to predict the atomic weight of the longest-lived member of the series, protoactinium. He mentioned that experimental verification of the suggested values was difficult owing to the great difficulty of separating protoactinium from tantalum.

Recently it has been shown in this laboratory that the separation of protoactinium from other elements is · not so difficult as has been thought, and about 2 mg. of almost pure oxide of protoactinium has been isolated. An account of this will shortly be published. The half-value period of this product has been redetermined by O. Hahn and E. Walling as 20,000 years For each gram of radium, therefore, in a mineral

there is approximately 0.4 gram of protoactinium.

It is hoped that the difficulties, both financial and technical, of preparing a sufficient quantity of the element for an atomic weight determination will soon be overcome so that this outstanding problem of radioactivity may be settled.

## Formation of Anthraquinone by Vapour-phase Oxidation of Toluene, and Toluene-containing Petroleum Distillates.

The recent paper of C R. Downs (Jour. Soc. Chem. Ind., 46, 383T; 1927), stating some facts and also speculations concerning catalytic oxidations, is of much interest, and we wish to confirm the interesting oxidation and condensation of toluene to anthraquinone. Experimental details of most of these vapour-phase reactions are almost entirely lacking, the processes being covered by numerous patents.

We have obtained small amounts of anthraquinone with benzoic acid and benzaldehyde by passing air mixed with toluene vapour, or the vapour of a toluenecontaining petroleum distillate, over a catalyst consisting of aluminum grains coated with vanadium pentoxide. The gas rate used was about 12 litres per hour, and the catalyst maintained at 400° C. The gas mixture was obtained by bubbling air through the toluene held at 50° C. The greater portion of the anthragumone and benzoic acid formed under these conditions crystallised out in the cooler parts of the exit end of the catalyst tube.

## Causes and Effects of Mining Subsidence.

By Sir Richard Redmayne, K C.B

THE final report of the Royal Commission on Mining Subsidence, appointed on Mar. 17, 1924, has recently been published. The Commission was asked to inquire into the operation of the law relating to support of the surface by underlying minerals, the extent and gravity of the damage caused by subsidence owing to the extraction of minerals, and to report as to what steps should be taken by legislation or otherwise to remedy equitably the hardships that may arise in existing conditions—a wide and controversial field—and Lord Blanesborough, the chairman, is to be congratulated, not only in securing unanimity, but also in having presented an admirable and lucid

The subjects of the report, which is concerned almost exclusively with the coal-mining aspect of the case as "the extraction of other minerals presents in this country no feature sufficiently outstanding to call for separate attention" at their hand, are considered under convenient heads which allow of the matter being easily and quickly digested. To the technical expert, perhaps, the matter dealt with under the earlier headings is the most interesting, namely—the physical aspects of subsidence, and the uncertainty of its incidence, as well as the definition of the problem before the Commission, the legal position. The definition given of subsidence is worth reproduction in view of some of the decisions that have been arrived at in the Law Courts. "Where," says the report, " a seam of mineral is completely extracted the unsupported roof falls If the overlying beds consist of comparatively soft strata, these will bend down gradually and fill the void almost completely, and the superincumbent beds will come down in turn until the subsidence reaches the surface. In every case the descent of the superincumbent strata is accompanied by more or less fracturing and, therefore, by an increase in the volume of the strata thus let down. It follows that the surface subsidence is never equal to the thickness of the mineral extracted.'

The full meaning which is meant to be conveyed by the words, "where a seam of mineral is completely extracted," is not clear. Literally interpreted, they would mean that the area of extraction involved would extend over the whole coalfield. The sentence should have read, "where a certain area of a seam of mineral is completely extracted." What that area has to be before subsidence commences has been a source of much argument in the Law Courts and elsewhere, is subject to variation, and is largely determined by circumstances, such as the thickness of seam worked, depth of the seam from the surface, inclination and nature of the strata overlying the seam, and the presence of faults. To maintain, as was asserted in a recent classic law case, that, on

<sup>1</sup> Second and Final Report of the Royal Commission on Mining Subsidence, Pp. 68, (London: H.M. Stationery Office, 1927.) Price 1s. 3d. net.

extraction of a coal-seam (only very small temporary support being left by odd pieces of coal which were left in the process of working), the roof, consisting of a strong bed of sandstone, would bend, and eventually a period of quiescence be attained without the roof and floor meeting, is a most erroneous view, but one more widely held than is generally supposed. It is pleasing, therefore, to find the Commission upholding the correct view and stating that the roof in such a case will break into comparatively large blocks which, piling up irregularly on each other, afford at the outset a certain measure of support to the overlying beds The presence of these beds gradually crushing down partly reconsolidates the broken blocks, and in this way the subsidence ultimately reaches the surface. The movement, too, continues longer, and the total amount of surface subsidence is less than when the superincumbent strata consist mainly of softer and more plastic rocks.

The Commission arrives at the conclusion that the amount of subsidence is not quantifiable and "cannot be predicted with any accuracy, even when all the conditions are tolerably well ascertained." I should hesitate to be so positive as this. Given the thickness of the seam, the method of working practised, the nature and thickness inclination of the superincumbent strata, it should be possible to arrive at a fairly close approximation, not only as to the amount, but also the period of the subsidence consequent upon extraction of the underlying mineral

The "problem of damage" from subsidence, as regarded by the Commission, can perhaps be epitomised thus

1. It may be better in the national interest in some cases to leave minerals unworked than to work them, for example, in such a case as where lowering the surface would cause the land to become a swamp

2. The determination of cases in which a remedy is called for where damage has been done to the surface and building, etc., where the owners have no claim for redress or compensation under existing conditions.

Most people are under the impression that the right of surface support is universal, but such is not the case. The right of support to the surface may have been lost through severance at some time of the ownership of the minerals from the ownership of the surface, but "unless the power to let down the surface be found in the instrument of severance," said Lord Swinfen (MR. 1915, 1 ch. 264), "and unless the power to let down the surface be found there expressly or by necessary implication, the common law of right of surface owner to support will prevail." Conveyancers in settling instruments of severance have devised provisions unambiguous in respect of power to

let down the surface, so there exists to-day in Great Britain a class of surface owner who has no right of support of the surface Again, the introduction of the Mines (Working Facilities and Support) Act, 1923, excellent measure though it is, has erected machinery for the purpose of enabling minerals to be worked irrespective, speaking generally, of the resulting effect upon specific surface property, and notwithstanding that, apart from the Act, the surface is entitled absolutely to support. In such a case the owner is entitled to, but he must be content with, pecuniary compensation.

The Commission recommends that private owners or occupiers of dwelling-houses of an annual value not exceeding £40 be entitled to compensation for damage to property arising from subsidence due to the extraction of adjacent minerals, such damage being manifest at the time of or subsequent to the passing of an Act allowing compensation, the compensation to be recoverable from any person who has worked the minerals under or adjacent to the house, which impresses one as being a wise and fair solution. The statement of the legal position, and the arguments which have influenced the Commission in arriving at this decision, are set out with admirable clearness and precision, and should be read with care by all of those interested in the subject, whether mining engineers, local authorities, lawyers, or property owners.

The remarks under the heading "Methods of Mitigating Subsidence Damage" are particularly interesting to the mining engineer Upon this aspect of the matter the report considers three suggestions, namely:

- (a) The hydraulic stowage of the excavated areas and more scientific methods of mining.
- (b) The scientific lay-out of the surface; and
- (c) Precautions possible in the construction of surface buildings.

As to the first, the conclusion is reached that the universal adoption in Great Britain of the filling of the mine wastes with débris under hydraulic pressure—a system so largely practised in the Pas de Calais, the Westphalian, and some other continental coalfields—is impracticable, chiefly because of the cost, a conclusion which was also arrived at a few years ago, for a similar reason, by the Government Committee on Spontaneous Combustion in Mines, of which the present writer was chairman. Except in a very few areas, such as South Staffordshire, where the circumstances in respect of the presence of the necessary material and underground conditions are more favourable to its introduction—at Motherwell, in Scotland, where it is being advantageously employed, the cost is estimated at 1s. 3d. per ton of coal raised.

Under a system of longwall working with regular advance of an even face and close and systematic packing of the goaf or waste, the subsidence resulting from the extraction of the coal is less than under the irregular working of coal. The longwall system is not, however, always practicable, for example, in the case of a very thick seam.

The disadvantage of erecting houses in long terraces, and the advantage of building them in blocks of two or four instead, is pointed out "The more scientific 'zoning' and development of the surface according to current conceptions of Town and Regional Planning should also do much to mitigate the damage caused by subsidence"

Under the third suggestion the Commissioners are impressed by the view expressed by Dr. Faber, who gave evidence before them, namely, that ordinary brick buildings would suffer much less from subsidence if lime mortar were replaced by cement mortar, the tensile strength of the latter being many times greater, the increase in cost not amounting to more than two or three per cent. The ordinary miners' cottage, he considered, would be perfectly safe "if built of ordinary brickwork with cement mortar on a properly constructed ferro-concrete raft."

The interests involved are classified by the Commission under three heads, namely (1) The National Interest; (2) the Local Authorities; (3) Private Owners

Under the first the matter involved has already been touched upon, namely, the possibility in some cases of the surface being rendered valueless by its being lowered. The Commission has the Doncaster area chiefly in mind, and in accordance with the recommendations made prior to the issue of this, the final report, a Commission of Inquiry has been set up.

The interests of local authorities in respect of possibility of subsidence are chiefly concerned with waterworks and sewage works. The Public Utility Companies, the Statutory Tramways Companies, and the Statutory Gas and Electricity Companies are likewise involved. Under the Railway Clauses Act, 1845, it is assumed that subsidence only takes place, more or less vertically, above the mineral workings—an assumption which all mining men now know to be erroneous—and a limit of forty yards was imposed as the distance beyond which the workings should not approach the thing to be supported. It was considered that the forty-yards' limit gave ample support from subjacent minerals

The special code of the Support of Sewers Act is a modification of the code in the Waterworks Clauses Act, 1847, the main difference being that the Local Authority may specify any distance within which they require the minerals to be left unworked. The matter in respect of railways has been modified by the Mines (Working Facilities and Support) Act, 1923, the statutory distance being enlarged to one-half the depth of the seam from the surface—though this is not a 'scientific' distance—and provides payment by the mineowner of partial compensation for damage caused by his workings within the statutory distance in cases where the right to purchase support has not been exercised by the railway company. The Commissioners are of the opinion that the right given under Part 1 of the Mines (Working Facilities and Support) Act, 1923, to prohibit and restrict the working of minerals should be extended to Local Authorities and Statutory Undertakings, which seems to be only right. It is to be hoped, however, that a more scientifically defined limitation in regard to the extent of lateral support to be left from subjacent minerals

will be devised than that existing in respect of

The exigencies of space prohibit a longer dissertation on this most valuable and interesting report, which is a model of conciseness and clarity, and should be widely and carefully read.

## The Chemistry of Hormones.

THE British Association has the advantage over a number of specialist societies in that it brings together investigators in different branches of science. It makes good use of this advantage in the joint meetings of cognate sections and by discussions on the border line between two sciences. In framing his programme for the Leeds meeting, the recorder of Section B (Chemistry) must have had these advantages in view, for he secured contributions from a number of physiologists to a valuable discussion on Sept. 5 on the chemistry of hormones.

In opening the discussion, Prof. G. Barger (Edinburgh) began by explaining what is meant by a hormone. In contradistinction to the longknown method of stimulation by a nervous impulse, Bayliss and Starling first recognised, in the case of secretin, that a stimulus may also be brought about by a chemical messenger or hormone, set free in one organ and travelling through the blood stream to another organ which is then excited to Thus the hormones are highly active and highly specific drugs which the body elaborates for its own uses. The preparation and study of the hormones is therefore of the greatest importance to medicine, since they may produce effects quite unobtainable by the ordinary vegetable or synthetic drugs. The recent introduction of insulin in the treatment of diabetes is a case in point.

With the aid of lantern slides, Prof. Barger illustrated the course of development of our knowledge by reference to the two hormones which have so far been synthesised, adrenaline and thyroxine. There is first the recognition by the clinician or physiologist of the importance of the organ producing the hormone. In the two cases mentioned, this was followed by the discovery in it of some chemical peculiarity (chromogen in the adrenal gland, iodine in the thyroid). The biochemist then attempts the isolation of the active substance in a state of purity, and when this has been achieved, the organic chemist can investigate the molecular structure of the hormone and finally synthesise it; when the physiologist certifies the synthetic product to have the same degree of activity as the natural substance, some degree of finality has been reached.

For this reason Prof. Barger did not deal with the constitution and synthesis of adrenaline and thyroxine as choses jugées, but focussed attention on the crystalline substance of high molecular weight, obtained recently from commercial insulin by Abel and his co-workers, and having in a high degree the physiological activity characteristic of this hormone. The substance can be recrystallised

and retains its activity; indeed, the residue left on evaporation of the mother liquor is, weight for weight, much less active than the crystals. This would constitute a prima facie claim that insulin has thus been obtained in a state of chemical purity, but Abel, aware of the pitfalls which beset investigations of this kind, himself suggests the alternative, that the crystals may carry down "an unknown substance of almost unbelievable potency." The carrying down of insulin by a crystalline precipitate of a much simpler substance, benzoic acid, formed in its solution, has actually been used in the manufacture of insulin.

Prof. Barger directed attention to the analogous difficulty in appraising the recent work of Jansen and Donath, who described the isolation of the enormously active vitamin from rice polishings. These authors crystallised a hydrochloride from acetone and alcohol, converted it into the crystalline picrolonate and gold salt, and passed back from these to the original hydrochloride without loss of activity. Here adsorption would seem to be excluded. In the case of insulin the substance can only be crystallised from water in the same way as it is formed originally, i.e. by the careful addition of ammonia to a highly buffered solution.

The subsequent discussion showed that this method did not entirely satisfy organic chemists. Prof. J. L. Simonsen compared it to the precipitation of barium sulphate; Prof. J. Mellanby pointed out the analogy to the crystallisation of proteins. A letter was read from Mr. F. H. Carr (unfortunately prevented from being present); he had carried out the crystallisation according to Abel's directions but found that the crystals were only one and a half times as active as the starting material (the ordinary commercial product of British Drug Houses, Ltd.). Others have also considered that the low potency of Abel's crystalline substance raises doubts as to its purity. This is, however only an argument drawn from analogy; pure insulin may be less active than other hormones, and the only ways of settling the matter would seem to be, either to get the same crystals with a much smaller potency, or to synthesise them; the latter would be a formidable undertaking.

Prof. Barger ended by putting forward a theory of the action of adrenaline and related amines, based on their adsorption by lecithin. He imagined the amino group of the hormone to be attracted by the phosphoric acid residue and the residual affinity of the acidic phenolic nucleus by the basic choline grouping; this would explain the optimal length of the side chain of two carbon atoms, the favourable effect of a phenolic hydroxyl, etc.

Prof H. S. Raper (Manchester) dealt next with the possible mode of formation of adrenaline in the organism. Although the organic chemist has disposed of adrenaline by synthesis, there is still work for the biochemist. Tyrosine appears to be the only possible precursor, and recently he has shown that this amino acid is actually changed by an animal oxidase to a catechol derivative, dihydroxy phenyl alanıne. The latter is then converted to an indole derivative, which might, however, not occur if the amino group is substituted.

Prof. J. C. Drummond (London) referred to the enormous activity of irradiated ergosterol in preventing rickets In his laboratory as little as 0 5-1 millionth of a milligram per day has lately been found sufficient for 100 grams of rat isolation of hormones is rendered difficult by a similar great potency. He referred to Abel's extremely active tartrate of a pituitary active principle, and to the fact that the same organ may produce several substances with different physiological actions Similarly, the investigation of the ovarian hormone is complicated by the existence of a substance, 'anti-oestrin,' balancing the action of oestrin

Prof. E C. Dodds (London) discussed the ovarian hormone, which he has been unable to distil, as described for example by Frankel and Herrmann, he doubts whether the active substance is really volatile. (The later experiments of Hartmann and Isler, who distilled the purified hormone after treatment with acetic anhydride, would seem, however, to leave little doubt on this point.) Prof. Dodds also questioned whether the

ovarian hormone is a lipoid, and considered that it has a true solubility in water. He referred to experiments with solutions of adrenaline in oil, which retained some pressor activity after shaking with dilute hydrochloric acid. In any case the chemical purification of the ovarian hormone does not seem sufficiently far advanced to draw many conclusions as to its chemical nature.

Prof J. Mellanby (London) described his experiments on the purification of secretin, which have resulted in an intensely active preparation, free from depressor substance. Contrary to Bayliss and Starling's view, that secretion is liberated from a 'pro-secretin' by acid hydrolysis, Prof. Mellanby considers that the substance is merely set free from an adsorption compound and in the normal process of digestion becomes fixed on bile acids. It is by adsorption on these acids that he has been able to effect so considerable a purification Adsorption (on fuller's earth) is also the most effective preliminary stage in the purification of vitamin B. Although highly active, Prof. Mellanby's secretin is not yet chemically pure, one of its most significant properties is the absence of any reaction with ninhydrin

In the general discussion, Dr. N. V. Sidgwick (the president of Section B), Prof. J. L. Simonsen, Dr T. A. Henry, Mr. H. J. Channon, and others took part, Prof. G. Barger replied. It was generally felt that the discussion had been valuable in bringing chemists and physiologists together to consider debatable border-line problems on which their outlook is apt to differ with the nature of

their studies.

## Obituary.

Prof. A. Liversidge, F.R.S.

THROUGH the death on Sept. 26 of Prof. Archibald Liversidge, science in Australia and New Zealand has lost one of the best and most unselfish of its friends. His death, due to heart trouble, in his eightieth year, came as a shock to his many friends, for even up to within a week or two of his decease he had always enjoyed robust health, and was exceptionally hale and hearty for his age. His nearest of kin surviving are his sister, Mrs. Balfern, of Buxted Lodge, Bexley, Kent, and his nephews Rear-Admiral E. Liversidge and Rear-Admiral J. G. Liversidge.

Born at Turnham Green in 1847, after studying at a private school and with tutors, Liversidge entered the Royal School of Mines and Royal College of Chemistry. Among his teachers were Frankland, Tyndall, and Ramsay. He gained an open scholarship in natural science at Christ's College, Cambridge, in 1867; and he was one of the two first students to work in Sir Michael Foster's physiological laboratory. After having been instructor in chemistry at the Royal School of Naval Architecture, he was appointed in 1870 demonstrator in chemistry at Cambridge. In 1873 he was elected to the chair of chemistry at the University of Sydney, a position which he held until

1908. He at once threw himself whole-heartedly, and with singleness of purpose, into the scientific life of his newly adopted country. His great energy, meticulous method combined with a breadth of outlook, a shrewd financial acumen and a keen desire to serve science for its own sake, at once marked him as a coming organiser.

Liversidge originated the Faculty of Science at the University of Sydney in 1879, serving as its dean from that date until 1904, and the University School of Mines in 1890 Thanks to him also the Royal Society of New South Wales now owns a fine scientific library and a valuable building as The first great impetus to technical education in New South Wales came largely from Liversidge, when a Member of the first Board of Technical Education at Sydney. As trustee of the Australian Museum, Sydney, from 1874 to 1908 he rendered invaluable service in helping to get together their fine collection, in greatly adding to their library, and in helping to secure for them their present fine building.

In 1885, Liversidge accomplished his greatest work in founding the Australasian Association for the Advancement of Science. Even those who know the relative isolation of scientific workers in Great Britain and Ireland previous to the founding of the

British Association can scarcely realise the extreme isolation of Australasian scientific workers separated from one another by distances as great as from London to Constantinople As in the case of the British Association, so, and even more so in the case of the Australasian Association, the crowning triumph of the work has been the bringing together for personal interchange of thought of so many remotely separated scientists

In regard to Liversidge's work at the University, as a teacher he was always remarkably successful and impressive with his practical demonstrations and lecture experiments Starting with very small buildings and next to no equipment, he was able, when he retired from the chair in 1908, to hand over to his successor, Prof Fawsitt, a large and flourishing school provided with laboratories, lecture-rooms, and equipment reasonably up to date in view of the great distance of Australian universities from centres of science in the old world

In spite of the time spent in teaching and organising, Liversidge's output of research work was considerable. His researches were directed chiefly to descriptive and experimental mineralogy. His chief published work was "The Minerals of New South Wales." He did much to stimulate interest in meteorites, collecting, analysing, and describing many Australian meteorites. Meteorites led him to study Australian meteoritic dust, especially the very finely divided red dust deposits which, in the hot dry climate of Australia, owe their origin to the transporting power of circular storms in the interior of the continent. He also published several papers on the origin and precipitation of gold, gold in solution in sea water, and the possible growth of gold nuggets in Australian alluvial

Altogether Liversidge contributed more than one hundred papers relating chiefly to chemistry and mineralogy, to the Chemical Society, the Royal Society of New South Wales, and the Royal Society of London. He made a hobby of acquiring minerals and meteorites, and his collections have frequently been displayed at exhibitions in Australia and in the northern hemisphere. Since retiring from the chair of chemistry at the University of Sydney, he continued until lately his researches at London laboratories. He was vice-president of the Chemical Society (1910 to 1913); vice-president of the Society of Chemical Industry (1909 to 1912); president of the Royal Society of New South Wales (1886, 1890, and 1901), president of the Australasian Association for the Advancement of Science (1888 to 1890); and vice-president of the British Association (1896). He was also a member of the Philosophical Society of Cambridge, of the Physical Society, of the Mineralogical Society of Great Britain and France, and he was elected a fellow of the Royal Society of London in 1882. Honorary degrees or memberships were conferred upon him by universities and scientific bodies, totalling thirteen in number.

Liversidge to the last was no less loval to Australia than to the mother country, and after his return to England he continued to correspond

overseas and to study carefully Australian journals, and if he found any matter needing his help either in Australia or New Zealand that help was freely given. Previously to the migration of Liversidge to Australia, the case of scientific men there might be described as that of quot homines lot sententiae, but after his years of residence there and the founding and fostering of the Australasian Association, men of science in Australia and New Zealand spoke with one voice, a voice which met with such a fine response in the visit to Australia of the British Association in 1914 and the Pan-Pacific Science Congress in 1923.

Liversidge's beautiful home and grounds, Fieldhead, Coombe Warren, Surrey, with the historie spring from which Cardinal Wolsey carried the water in large lead pipes all the way thence, with a dive under the Thames, to Hampton Court, was for many years past the Mecca of pilgrims of science from Australia There, too, he frequently entertamed—for he loved hospitality—not a few of his old colleagues whom he used to meet regularly at

the Athenæum.

One thing surely stands out among the many for which Liversidge will be gratefully remembered, and that is his splendid striving for the fraternity

" Frater ave atque vale." T W. E. D.

PROF. GOSTA MITTAG-LEFFLER, FOR MEM. R.S. The mathematical world is appreciably poorer by the death of Mittag-Leffler, of Stockholm, who died there on July 7 last. He was born at

Stockholm on Mar. 16, 1846

For the best part of his long life of eighty-one years, Mittag-Leffler had been a proud standard bearer in the extraordinary march of the theory of functions during the nineteenth century. How wonderful the progress has been we may realise by comparing the scope of some of the earliest with that of some of the latest publications. A sort of warning is given by the title of Lagrange's volume, dated Prairial, an V. (Second Edition, "Théorie des fonctions analytiques, contenant les principes du Calcul différentiel dégagés de toute considération d'infiniment petits ou d'évanouissans, de limites ou de fluxions, et réduits à l'analyse algébrique des quantités finies." But compare its contents with that of Weierstrass's posthumous paper, published in 1903, "Allgemeine Untersuchungen über 2n-fach periodische Functionen von n-Veränderlichen"; this is described by Mittag-Leffler as only a fragment of Weierstrass's "Losung des Rätsels dass sein ganzes Leben in Anspruch genommen hat," which remains, he says, in 1916, "noch eine ungelöste Aufgabe, eme der grossten, die den Mathematikern unserer Tage obliegt." Think of the contributions of Abel, of Cauchy, of Gauss, of Jacobi, of Riemann, of Weierstrass, of Poincaré, and of others, who, from the first recognition that the generally warrable the first recognition that the complex variable is the natural foundation of a general theory, have steadily erected a structure of constantly increasing grandeur and beauty.

Of all this progress in the branches of mathematics to which he was devoted, Mittag-Leffler was an enthusiastic observer, and, of its later phases, a conscientious historian, and he took upon himself the mission of fostering, in every way he could, amicable relations between mathematicians of different nationalities, and encouraging a disinterested pursuit of high intellectual aims, unaffected by any political or material bias With evident joy he tells how, three years after " la funeste année 1870 " " je vins à Paris suivre le cours d'Hermite; je n'oublierai jamais la stupéfaction que j'éprouvai aux premiers mots qu'il m'addressa 'Vous avez fait erreur, Monsieur,' me dit-il, 'vous auriez dû suivre les cours de Weierstrass à Berlin C'est notre maître à tous' Hermite était Français et patriote, j'appris du même coup à quel degré aussi il était mathématicien" But Mittag-Leffler was more than a standard-bearer of a mighty army; he was keenly anxious for the success of his subject He quotes Weierstrass's plea for the unity of all scientific endeavour, "Die einzelnen wissenschaftlichen Disziplinen erhalten ihre Bedeutung dadurch, dass sie alle zu diesem Zwecke mitwirken—in dem Mitund Nacheinandersein der Dinge Ordnung und gesetzmassigen Zusammenhang zu entdeckenaber nicht zusammenhanglos, sondern gleichsam eine Kette bildend" But he is aware of the conflict of his own subject with others whose aims have a more popular appeal, and when, in 1916, on his seventieth birthday, he devotes his house and library to the perpetual service of research in pure mathematics, he writes (Actu Math., 40), "Peu de gens, en dehors des spécialistes, comprennent l'importance et la mission des mathéinatiques pures," "un peuple que n'accorde pas aux mathématiques un rang élevé dans son estime, ne sera jamais en état de remplir les plus hautes tâches civilisatrices et de jouir, par suite, de la considération internationale"

Mittag-Leffler was the son of J O Leffler, headmaster of a secondary school, and of G. V. Mittag He was university lecturer in 1872 at Upsala, where he took his doctor's degree. After three years of travel (1873–1876) in Germany and France, he was professor of mathematics at Helsingfors until 1881, when he became professor at Stockholm (and Rector in 1885-6 and 1891-2). He resigned this post in 1911. In 1882, with an editorial staff of mathematicians from the four Scandinavian nations, and under the patronage of King Oscar II. of Sweden, he founded the journal Acta Mathematica, having noted, as he explains, that, after 1870, the German Crelle's Journal, and the French Liouville's Journal, had both ceased to have an international character. Of his own journal he remained editor in chief for forty years, until Vol. 40 (1925), maintaining, through this long period, it may safely be said, both the devotion to modern developments and the high standard set by Poincaré, in expounding his theory of Fuchsian functions in the early volumes. Special volumes were devoted to papers sent from all parts in commemoration of the

centenary of the birth of Abel (1902), a volume (38, 1921) was given to contributions by various writers in memory of Poincaré, and a volume (39, 1923, 258 quarto pages), written largely by Mittag-Leffler himself, is in effect a first hand critical history, of extreme value and interest, of the ideas associated with the names of Weierstrass and Poincaré. Beside the 57 pages dealing with the personal history and work of Weierstrass, this volume contains a paper of 65 pages largely composed of letters from Weierstrass to Sonja Kowalewsky Mittag-Leffler was in a good position to write, as he had collected the necessary documents over many years

The latter paper directs attention to another side of Mittag-Leffler's activity, and helps also to a better understanding of a book written by his sister, Anne Charlotte Leffler (Mme. Eddgren, and, later, Duchess of Cajanello); this is a biography of Sonja Kowalewsky, written in continuation of the autobiography of the early years of the latter; it is a book which every one who is interested in contemporary intellectual movements will have, or should have, read. It appears that after Mme. Kowalewsky had spent her four student years with Weierstrass (in continuation of her studies at Heidelberg), and was settled in Russia, it was suggested by Weierstrass to Mittag-Leffler, then in St. Petersburg, that he should call on Mme. Kowalewsky. The final outcome was that, very soon after Mittag-Leffler had been appointed professor in Stockholm, he took great trouble to open the way for Mme Kowalewsky to settle there as lecturer in mathematics Of his admiration for her personality, and of his feeling that he was doing a great thing for higher education, and for Stockholm, there is ample evidence—there is also evidence in Weierstrass's letters to Sonja of the regard which he had conceived for the personality of Mittag-Leffler. The end of the experiment at Stockholm is given in graphic phrase in the book referred to The gist seems to lie in A Ch Leffler's description of Sonja's "ardent besom d'intimité intellectuelle, et de la souffrance intense que lui causait le sentiment de la solitude . Le travail par lui-même, la recherche abstraite d'une vérité scientifique, ne la satisfaisant pas, il fallait qu'elle fût comprise, devinée, admirée, encouragée à chaque pas, à chaque nouvelle idée qui naissait en elle . . . Mittag-Leffler disait souvent à ce sujet, que ce besoin d'être comprise était chez Sophie une faiblesse de femme; un homme de génie ne dépend jamais ainsi de la sympathie des autres '

It will be gathered from what has been said how important was the service of Mittag-Leffler, as a link, as a sort of gracious master of the ceremonies, for one aspect of modern mathematics, it were to be wished that in England we gave more of the reverent care which animated him, to the historical and personal side of the development of the subject. His own personal contributions to the theory of functions need no long comment here. One of his

<sup>1 &</sup>quot;Souvenirs d'enfance de Sophie Kovalewsky, suivis de sa biographie" (Hachette, 1895). Also in Swedish, German, and English (Walter Scott)

papers, dealing with the formation of a function of which the behaviour at its singular points is specified a priori, was the occasion for a paper presented to the Berlin Academy, in association with the name of Mittag-Leffler, by Weierstrass. It is perhaps opportune to remark that the intimately related construction, by Weierstrass, of an integral function with given zeros, which one might naturally have thought to be suggested by Gauss's factorisation of the gamma function, was given only in 1874, when Weierstrass was fiftynine years old (letter to Sonja Kowalewsky, Acta Math, 39, 151). and that the form of Gauss's factorisation which exactly suggests the general

theorem was given in 1848, by F W Newman, in the Camb and Dublin Math Journal, 3. This was remarked by the late G B Mathews in the pages of Nature, long ago; it is not referred to by Mittag-Leffler in dealing with Weierstrass's early investigations (1843, 1856) on the analytical Facultaten. Another matter of a different kind occupied Mittag-Leffler in a series of papers: the expression of a function, with singularities for finite values of the independent variable, in a form which is valid over the whole plane as dissected by lines passing to infinity from the singular points of the function. Other papers, many written in Swedish journals, are not as yet so well known

## News and Views.

AGRICULTURE is the oldest of the chemical industries. The business of feeding man and his friends has, fortunately, been able to jog along for a very long time without entering into any close relationship with synthetic chemical industries other than that carried on so universally and so successfully by certain of the lower organisms of the soil. There has, moreover, been a disinclination to apply some of the new knowledge that has been placed at the service of the farmer, it being dismissed as being of little consequence when compared with the accumulated practical experience of generations on the land. Doubtless, too, the lack of consideration has not all been evidenced on one side However this may be, it is a fact that we cannot continue indefinitely to live on the reserve fertility of the virgin plains of the earth. Sir Alfred Mond, in an address read before the delegates to the Imperial Agricultural Research Conference at Billmgham on Oct. 18, based his remarks on this truism, and on the part which synthetic chemical industry must play in the future development of agriculture. So far as the British Empire is concerned, the economic aspect of the situation is no less considerable than the scientific. As was pointed out in the address, for many years Europe has paid to South America millions upon millions of pounds for nitrogen in the form of guano or of sodium nitrate. Imperial Chemical Industries, Ltd., has set itself the ambitious task not only of supplying the whole Empire with fertilisers, but also of acquiring and disseminating information concerning their application to soils of varying qualities and varying needs.

NITRAM, LTD., the selling organisation which has been set up to deal with the new synthetic fertilisers, has, said Sir Alfred Mond, already instituted a free and disinterested advisory service to farmers. It has also established a research station, with upwards of 400 acres of farm lands, where problems relating to the use of fertilisers and to the feeding of stock are to be investigated. The activities at Billingham, however, will not be confined to the manufacture of simple synthetic nitrogenous fertilisers, but will extend to the production of compound fertilisers, containing nitrogen, phosphorus, and potassium—the three chief plant foods—according to the demands of experi-

ment and experience. Naturally, the fertiliser requirements of the British Isles will be the first to receive attention.

A Careful consideration of Sir Alfred Mond's address leads one to the conclusion that, although he had no startling or even new thesis to present, he was able to show that Imperial Chemical Industries, Ltd., fully realises the nature of the problem—that of most effectively using chemical and mechanical knowledge in the multiplication of the fruits and riches of the earth—in its future as well as in its present aspects, and that the organisation is solving it in a patriotic as well as in a commercially successful manner. It is not merely a question of there being so many more mouths to feed and bodies to clothe each year. Neither is it entirely a question of meeting a demand for a more varied food supply; for satisfying the requirements of a generation better instructed. than its fathers in the relation of diet to health. There is also an increasing demand from the chemical industries themselves for new material. The artificial silk industry is a case in point; the alcohol motorfuel industry is another; and man has only just begun to learn the rules for training bacteria, in 'commercial numbers,' to do his will.

THE Slaughter of Animals (Scotland) Bill, which comes before the House of Commons for its third reading on Nov. 15, provides for the licensing of slaughtermen in order to check unskilful slaughtering, and for the stunning of animals with a mechanically operated instrument before slaughter. At the committee stage considerable concessions had to be made to the opponents of humane slaughtering: the effect of the bill was restricted to slaughter-houses and knackers' yards, swine were exempted from the operation, and the usual exemption for Jewish slaughtering was introduced. While the first two, at least, of these concessions will be generally regretted by humanitarians, there can be no doubt that they were wisely made, for in exchange the opponents of the bill have undertaken to allow it to pass into law. Indeed, the Government would not need any great courage to adopt the bill as its own during the final stages. The subject is to be discussed at a debate arranged by

the University of London Animal Welfare Society at Birkbeck College, Bream's Buildings, Chancery Lane, at 8 P.M. on Friday, Nov. 4. The principal speakers will be Mr. A. C. Dewbury, representing the Royal Society for the Prevention of Cruelty to Animals, and Mr. A. C. Knight, representing the Meat Traders' Federation; the chair will be taken by the president of the University society, Prof. F. T. G. Hobday, principal of the Royal Vetermary College The public will be admitted to the debate without ticket

Dr. William G. Savage delivered the Malcolm Morris Memorial Lecture (under the Chadwick Trust) on Oct. 17, the subject being "Food Poisoning." After paying a tribute to the memory of Sir Malcolm Morris, the lecturer said that food poisoning in the main is a result of the complexity of our food supply and might be classified thus: (1) the poison is inherent in the food, eg poisonous fish; (2) the poison may be an admixed poisonous substance accidentally introduced, e.g. arsenic; or (3) the poison may be of bacterial origin, by far the largest class. Earlier conceptions of food poisoning were dominated by the idea that the poisoning was from decomposed food in which poisonous chemical substances were generated by bacterial action, and this was commonly known as 'ptomaine poisoning.' This idea is, however, entirely erroneous—there is no such thing as ptomaine poisoning. Tainted food does not as a rule cause food poisoning; in nearly all cases the food is perfectly good physically. The cause is elsewhere, and is generally due to certain special bacilli gaining access to the food and having poisonous properties but do not decompose the food; it is a definite infection of the It is particularly manipulated and much handled foods that become infected, such as chopped meat, meat pies, sausages, and canned foods. The bacilli usually gain access to the food from an outside source, through lack of adequate care in preparation or storage, or by contamination through flies or vermin The prevention of food poisoning depends upon a knowledge of where the bacıllı live and how they gain access to the food, and in adequate supervision of the preparation and storage of made-up foods.

The stone implements recently discovered by Mr. J. P. T. Burchell in Co. Sligo, Ireland, will be on exhibition in the rooms of the Society of Antiquaries of London, Burlington House, Piccadilly, between the hours of 10 a.m. and 6 p.m. from Monday, Nov. 21, until Tuesday, Dec. 6, inclusive. The rooms of the Society will be closed to the public at 1 p.m. on the following dates: Nov. 23, 24, and 26, until 10 a.m. Monday, Nov. 28; Dec. 1 and 3, until 10 a.m. Monday, Dec. 5

The Huxley Memorial Lecture of the Royal Anthropological Institute for the year 1927 will be delivered by Dr. Aleš Hrdhčka, of Washington, on Nov. 1, at 8.30 p.m., at the rooms of the Royal Society, Burlington House. Dr. Hrdhčka has taken as his subject "The Neanderthal Phase of Man"—a subject which he has made peculiarly his own and upon which he may be expected on this occasion to

put forward views of no little importance for the study of early man. At the conclusion of the lecture the Huxley Memorial Medal of the Institute will be presented to Dr. Hrdlička. Tickets for the lecture may be obtained on application to the Hon. Secretary of the Royal Anthropological Institute, 52 Upper Bedford Place

MISS CATON-THOMPSON has left for Egypt, where, during the coming winter, she will continue her work of exploration in the Northern Fayum. She proposes this year to devote herself to an examination of the graves in the hope that she may be able to find material which will throw light upon the dating of the early civilisation of this area which she has discovered in her previous season's work. A very high antiquity has been attributed by some authorities to this remarkable culture. If, therefore, the investigations of this year should meet with any measure of success, the results should prove of very special importance. As the arrangements under which Miss Caton-Thompson has worked hitherto have now lapsed, the present expedition is being carried on under the direction of the Council of the Royal Anthropological Institute, which has applied to the Egyptian Department of Antiquities for a concession. The Council of the Institute invites subscriptions towards the cost of the expedition, which will amount to at least £1000. Contributions should be addressed to the Hon Treasurer, Royal Anthropological Institute, 52 Upper Bedford Place, W.C.1.

Among the recent acquisitions at the British Museum (Natural History), we notice the following:-A large collection of mammals, birds, and birds' eggs from Abyssinia; a large collection of leeches, earthworms, tapeworms, etc., and a collection of millipedes from Colombia, and two shells of the extremely rare and much prized gastropod Voluta bednalli. Only two or three examples of this species are known. A collection of European and exotic Coleoptera and of Hemiptera Heteroptera (plant bugs) bequeathed by the late Mr. G C. Champion. The major portion of the bequest consists of some 120,000 beetles from various parts of the continent of Europe, forming probably the richest European collection in Great Also a collection of 8406 Lepidoptera (butterflies and moths) presented by Mr. G T. This donation includes a large Bethune Baker. number of types and paratypes of species described by its late owner, as well as 5574 specimens of British Tortricidæ (small moths, many of them of great economic importance), comprising the entire collection of these insects formed by Mr. Richard South. About 500 seeds and fruits collected by the donor, Miss M. Chandler, in the Upper Eocene clay of Hordle, Hants, and described by her in the monograph of the Palæontographical Society. Many of these are new to science; the whole flora shows relations to that now living in the Far East, and indicates a warmer clunate. Some fine ammonites and other fossil cephalopod shells recently collected from the Gault of Dorset have been presented by Lt.-Col. R. H. Cunnington, and the Gault of Glynde, Sussex, has yielded to the careful search of Mr. C. T. A. Gaster nearly a thousand tmy ammonites belonging to about 14 species. The Lower Perman Sandstones near Exeter have from time to time yielded footprints and other tracks of extinct animals, and Mr. Clayden has added to the national collection four slabs with very unusual tracks of origin as yet unexplained

An Italian Aictic expedition by airship is being planned for next year. The Times announces that the expedition will be organised and led by General U. Nobile, who accompanied Capt R. Amundsen in his polar flight in 1926 The Italian government has offered airship N 4, which is a sister ship of the Norge. used on that occasion, and the Norwegian Aero (lub has promised the use of airship sheds at Vadso and Kıng's Bay. General Nobile intends to make his Arctic base in Spitsbergen and to explore eastward to the north of Siberia, intending no doubt to throw light on the unknown northward extension of Nicholas Land. He proposes also to make a flight to the Pole. The Soviet Government has expressed a wish to help by establishing a base with supplies at the mouth of the Yenisei River. At present a committee at Milan is considering the cost of the project. The Royal Italian Geographical Society has promised its support.

The newly formed Greenland Association of Copenhagen, which is seeking to open up this great sub-Arctic territory, learns that the University of Michigan, U.S.A., is sending a scientific expedition to this great island to study and report on the meteorological conditions prevailing there. The expedition will be under the charge of Herr Helge Bangsted, who proposes to build an Ice-station somewhere in the centre of Greenland, where the condition of the great ice-cap will be studied and general glacial researches made. Mr. Bangsted, it may be remembered, was a member of the Knud Rasmussen expedition to Greenland sometime ago.

An original suggestion has been made to Signor Mussolmi by an engineer and architect named Pio Franchi. His idea is to execute an exact model, in high relief, of the Italian peninsula from the Alps to Cape Passaro, the southernmost point of Sicily, to be placed in a miniature lake sixty metres in diameter, representing part of the Mediterranean and Adriatic Seas, with the exact imitation of every geographical detail-mountains, rivers, lakes, towns, railroads, etc. The principal rivers, such as the Po, the Tiber, and the Arno, would be represented by rivulets of running water, reproducing the exact curves. It is proposed to place this relief model in the Villa Umberto, the object being to give children and the general public a clear idea of their country. The idea has, says the Monitor, met with the Duce's approval, so that it will be shortly carried out.

THE eighteenth annual exhibition of electrical, optical, and other physical apparatus, organised by the Physical Society and the Optical Society, is to be held on Jan. 10–12, 1928, at the Imperial College of Science and Technology, South Kensington. The exhibition committee invites offers from research

laboratories and institutions, and from individual research workers, of suitable exhibits for the research and experimental section of the exhibition. Offers of exhibits in this section should be communicated immediately, and in any case not later than Nov. 16, to the secretary, Physical and Optical Societies, I Lowther Gardens, Exhibition Road, London, S.W.7.

At the annual statutory meeting of the Royal Society of Edinburgh, held on Oct 24, the following officers and members of council were elected.—President, Sir James Ewing, General Secretary, Prof. R. A. Sampson, Treasurer, Dr. J. Watt; Curator of Library and Museum, Prof. D'Arcy W. Thompson, Councillors, Prof. G. Bargei, Mr. J. Bartholomew, Prof. G. Darwin, Prof. D. Waterston, Mr. J. W. Peck, Dr. J. Ritchie, Prof. R. Stanfield, Dr. A. L. Turner, Dr. G. W. Tyrrell, Prof. J. H. Ashworth, the Hon. Lord Constable, Prof. E. Taylor Jones.

VIOLENT earthquake shocks were recorded in various parts of the United States and Canada on Oct. 24. The greatest disturbances seem to have been registered between 11 a.m. and 11.20 Mr. J. J. Shaw, of West Bromwich, records in the *Times* that his instruments registered large movements, beginning just after 4 p.m. on Oct. 24, which corresponds to 11 a.m. Eastern time, and continuing until about 5 20.

THE Report of the Progress of the Ordnance Survey for 1926-27 has been published (London Stationery Office. 9d. net) Among the achievements may be noted the completion of the "Popular Edition" of the 1-meh map of England and Wales, and the publication of fifteen sheets of the same map of Scotland, making a total of twenty-five sheets of that country. The 10-inch map of Great Britain is now complete in three sheets, the 1/M physical map of England and Wales is being improved, and a similar map of Scotland is in hand. The usual revision in the field of the large-scale maps has been carried out, but the reversion to quarter sheets of the 6-meh man has caused some delay in publication. A revised edition of the map of Roman Britain will shortly be ready. A considerable amount of archeological work has been undertaken. Lastly, it may be noted that the output of maps, exclusive of those for other departments, reached more than three-quarters of a million, and sales of maps showed a marked merease.

The long spell of wet weather in Great Britain that began in June and continued with extraordinarily few breaks up to the end of the holiday season, had a very abrupt end when a ridge of high pressure advanced from the Atlantic on the night of Oct. 2 behind an unusually fast-moving depression which had caused gales and very heavy rain in the north. A general sustained upward 'surge' of the barometer then occurred over a wide area, and this converted the 'ridge' into a large circular anticyclone in the space of twelve hours. At 7 a.m. on the morning of Oct. 3 this anticyclone lay centrally over the British Isles, and was still growing in size. It proved very persistent, and inaugurated a long spell of dry weather over the whole country. At Kew Observatory slight rain fell on

Oct 1 and 2, amounting altogether to two millimetres, but from then up to the 21st there was an unbroken succession of days with no rain or only a fraction of a millimetre. At Glasgow and Plymouth a dry spell of almost equal length has been recorded, which would have been a general experience over practically the whole of England and a large part of Scotland but for some local rain in the Midlands and the north on Oct 12. This has been the longest spell of drought at Kew this year, and unless some decided change takes place, October, normally the wettest month, may prove to be for London very much the driest in the present year

The Compton medal of the Institution of Automobile Engineers has been awarded to Mr. H. R. Ricardo for his paper entitled "Some Notes on Petrol-Engine Development."

The Cambridge University Press will shortly publish "A Short History of Western Civilisation," by Prof. A. F. Hattersley, the aim of which is to trace the origin and growth, in its essential features, of the European civilisation of to-day. The same publishers are also issuing "The Antiquity of Man in East Anglia," by J. Reid Moir, who has endeavoured to give an easily understood account of the remains discovered in Norfolk and Suffolk which, in many

cases, are of such a nature as to have implications extending far beyond the relatively small area in which they were found.

Applications are invited for the following appointments, on or before the dates mentioned :- A pathologist and curator at the Royal London Ophthalmic Hospital—The Secretary, Royal London Ophthalmic Hospital, City Road, E C I (Oct 31) A lecturer in the pharmacy department of the Sunderland Technical College—The Chief Education Officer, 15 John Street, Sunderland (Nov. 7). A farm duector at the Rothamsted Experimental Station-The Secretary, Rothamsted Experimental Station, Harpenden, Herts (Nov. 14). A chemical assistant in the laboratories of the Research Association of British Flour Millers-The Director of Research, Research Association of British Flour Millers, Old London Road, St. Albans. teacher in mechanical engineering at the Barnsley Mining and Technical College—The Principal, Mining and Technical College, Barnsley. An engineering assistant in the electrical engineer's department of Stoke-on-Trent — The City Electrical Engineer, St. George's Chambers, Kingsway, Stoke-on-Trent clinical pathologist at the Crichton Royal Mental Hospital, Dumfries—The Physician Superintendent. Crichton Royal Mental Hospital, Dumfiles

#### Our Astronomical Column.

Brilliant Meteors on Oct 17—Mr. W. F. Denning writes that "on the night of Oct. 17 three brilliant meteors were visible at the following times respectively: 21h 55m, 22h 15m and 23h 36m. The inctor of 22h 15m was a Capricornid; the other two were fine Orionids. The one which appeared at 23h 36m was a very brilliant object and observed from Yorkshire and from Erith, Kent. The meteor passed from over Cromer to east of Nottingham, and fell from a height of 86 to 52 miles. The luminous flight was about 92 miles long, and the velocity 38 miles per second. The maximum of the Orionid shower usually occurs on Oct. 20 or 21, and the appearance of several large meteors from it as early as Oct 17 mduces the supposition that the display may have been of rather unusual richness this year."

The Atmospheres of the Giant Planets —The Scientific American for October contains an article on this subject by Prof. H. N. Russell, who writes from the Lowell Observatory, Flagstaff, and utilises many of the beautiful planetary photographs obtained there by Dr. E. C. Slipher, some of which are reproduced. (A small slip should be noticed; the markings seen on Saturn in 1876 and 1903, and used for finding the time of rotation, are described as dark instead of bright.)

The radiometric observations of Coblentz and Lampland are quoted as proving that the outer regions of the atmospheres of the giant planets are at a very low temperature; but that, as there is a series of cloud layers many thousands of miles thick, these would be an effective blanket to outward radiation, and the temperatures at the surfaces of the planets may be much higher.

As is well known, the spectra of these planets show a series of strong absorption bands, which steadily increase in strength as we travel out from Jupiter

to Neptune. This suggests that a very low temperature is required for their production, the suggestion is made that, if a long tube were cooled by a surrounding jacket of liquid air and filled with various gases, a study of their spectra might give a clue to the identification of the gases producing the bands. It is noted as a possible clue that some of the oxides of introgen can be protected from decomposition only by keeping them very cold. The great variety of colours seen on the discs of Jupiter and Saturn is given as an additional proof that a large number of gaseous compounds are present.

of gaseous compounds are present.

The photographs that are reproduced were taken in light of different colours. As might be expected, those in violet light show much greater darkening at the limbs, for the same reason that the setting sun looks red. The polar regions of Saturn are especially dark. The light from the ring, when photographed in yellow light, looks about equal to that from the middle of the disc, but in violet light the ring is the brighter.

Tables for Motion in an Ellipse.—Dr Innes has published a very useful table, giving the abscissar and ordinates of a point describing an elliptical orbit under gravitation. The focus is the origin, and the major axis is the axis of x. The values are given to five places of decimals, the semi-major axis being taken as unity. They are given at intervals of one degree of M, the mean anomaly, and for intervals of 0.01 in the eccentricity, extending from 0.00 to 1.00. The tables are mainly intended for work with rectangular co-ordinates, but they are also very useful for those who prefer polar co-ordinates, since  $\tan v = Y/X$  and r = X sec v or Y cosec v. Similar tables have appeared before, but not on quite such an extended scale. They are useful both in the computation of ephemerides and of perturbations. They form an appendix to Umion Observ. Circular, No. 71.

## Research Items.

CLIMATIC CONTROL OF WHEAT AND WOOL IN Australia -Mr. Henry Barkley, the Senior Research Meteorologist of the Commonwealth Weather Bureau, has published preliminary results of the control exercised by rainfall during critical periods on production in Australia. The first paper (Wheat and Grain Review, Aug. 6) shows that after allowing for the gradual improvement due to improved methods, 90 per cent. of the variations in the Victorian wheat harvest depend on fluctuations of the rainfall in August and September, thus enabling a very good forecast to be made two months ahead. The relationship is not linear, but the wheat yield is roughly proportional to the logarithm of the rainfall. In other parts of Australia the critical periods vary from June to August. Another interesting result which the author obtains is that there is very fair agreement between the spring wheat yields of Victoria and the contemporary autumn yields of Canada and, until 1916, Russia This is attributed to a general control of the climates of all three countries by solar variations, which cause a cyclic change of roughly three years. Mr. Barkley's second paper (Pastoral Review, August) deals with the control of the wool yield in November by rainfall as early as January and February. The relationship is again very close; the weight of the wool clip shows a progressive increase as the rainfall of the two months together rises from 1 to 4½ inches; the latter is the optimum value and heavier rain causes a slight falling off. It is not yet clear, however, whether the increase of weight represents a real gam of that amount, or whether it is partly due to an increase of greasy matter, and further data are required to settle this and some other doubtful points. It is to be hoped that Mr. Barkley will be able to continue these valuable researches, which have a direct bearing on Australian production.

CANADIAN SALMON.—Few observations have been made on the biology of the Atlantic salmon (Salmo salar) from Canadian waters, and a recent publication by W. L. Calderwood on the salmon of the River Grand Cascapedia in the Quebec Province is welcome (Proc. Roy. Soc. Edinburgh, vol. 47, pt. 2, No. 10, 1927). The number of scales examined was unfortunately low, but they appear to furnish information of considerable interest. The smolt ages were remarkably high, the three and four-year-old smolts forming 58.8 and 34.1 per cent. of the whole respectively. There were no one-year-old smolts and two were five years old. In this respect they resemble those from certain northern rivers in Norway, although they do not agree with results from the River Moisie in Čanada, which hes north of the Grand Cascapedia, where two-year-old smolts were the most common. There were no grilse, neither were there any small spring fish represented in the samples. In fact only eleven fish returned after two winters in the sea, while the majority did so after three winters. though the fish do not come into the fresh water early because the river is not open, no summer feeding appears on their scales. The fish of the predominant three-winter group averaged 23.6 lb. and the average length was 38.3 in. Of the 182 fish, 62 had spawned previously—48 once and 14 twice.

Tanning Materials of Australia.—The Council for Scientific and Industrial Research of Australia has just published a survey of the tanning materials of the commonwealth (Bulletin No. 32, by D. Coghill).

The survey was designed to explore the possible commercial resources of Australia in vegetable tanning materials. With this end in view, all the barks, woods, twigs, leaves, and fruit from which tannin could be extracted have been examined, and their possible utilisation discussed. While no new sources of importance have been discovered, the availability and quantity of the tannins previously known have been thoroughly re-examined, with the view of establishing a flourishing tannin extract industry in Australia Western Australia is rich in natural sources of tannins, while the eastern provinces provide a fertile and broad ground for the cultivation of those species which give a good yield of tan bark, and grow quickly. The proposition is a praiseworthy one. New sources of tannins are urgently needed. Already Australia has to import some of her tan extracts, and during the last few decades there hasbeen an increasing dependence of the older countries on tan stuffs imported from new and less-developed regions, a condition of things accentuated recently by the ravages of the chestnut blight, which is seriously reducing the supplies of tanning materials obtained from that tree.

STIMULATION OF PLANT ACTIVITY. - Many chemical substances, apart from those ordinarily recognised as fertilising elements or yielding energy to plants by oxidation, are known to increase in several ways the rate of growth. F. E. Denny, of the Boyce Thomson Institute for Plant Research, discusses some such effects (Proc. U.S. Acad. Sciences, vol. 13, July 1927). The yellowing of commorcially mature but still green lomons and oranges may be very much accelerated by exposure to minute quantities of ethylene gas -- one part or less in 10,000 parts of air. A study of the respiration of lemons so exposed showed that the physiological activities of the fruit were greatly increased, the rate of production of carbon dioxide being doubled or trebled in 48 hours. So far, the mechanism of this respiratory increase is unknown. Furthermore, the stumulating effects of ethylene are not confined to Citrus truits, for Rosa found that the rest period of dormant buds of potato could be shortened by suitable treatment with that gas. Denny now finds that several chemical agents will break the rest period of plants; e.g. ethylene chlorhydrine, ethylene chloride, various thiocyanate solutions, acetaldehyde. The chemicals that were found to cause stimulation varied greatly in character, so that no evident relation could be established between the type of chemical used and the result obtained. In most cases it did not seem possible that the substance was used by the plant directly as food, and in no case could it have supplied. sufficient energy to account for the resulting increased activity. Now Carrol and Baker found that the substance in embryonic tissue which markedly stimulated multiplication of isolated cells was the product of the partial hydrolysis of a protein. The present author suggests that possibly the slight miury produced by those chemical stimulants may cause a slight and partial decomposition of constituents of the tissues, resulting in the release of growth promoting substances which start up renewed cells division and bud growth.

ORIGIN OF MUTATIONS—Some experiments by Dr. A. M. Banta and Mr. T. R. Wood of the Station for Experimental Evolution at Cold Spring Harbour are described in a recent bulletin of Science News Service of Washington. Dr. Banta has been investi-

gating the genetics of Cladocera for many years, growing great numbers of them in water bottles under controlled conditions. One mutation which appeared recently failed to thrive under the ordinary conditions, but flourished and multiplied when kept in water at a higher temperature. It is suggested that the organisms inhabiting hot springs have originated in a similar way, through mutations adapted to high temperature conditions occurring near a hot spring where their descendants could reach the environment necessary for their prosperity.

NORTHERN CYCLOSTOMES AND ELASMOBRANCHS -Recent additions to the fishes in "Die Tierwelt der Nord- und Ostsee" (Leipzig: Akademische Verlagsgesellschaft. 1927) are the Cyclostomes (Cyclostome, by W Schnackenbeck, Teil XII. d), and the Elasmobranchs (Elasmobranchu, by E Ehrenbaum, Teil XII. e). The cyclostomes in this area consist of three genera, each represented by one species, namely, Petromyzon marinus, the sea lamprey, Lampetra fluviatilis, the liver lamprey; and Myxine glutinosa, the hag-fish. The true fresh-water lamprey, Lampetra planeri, although mentioned in this work, does not strictly come within its limits Dr Ehrenbaum gives a good account of the elasmobranchs. monstrosa is the only representative of the Holocephali in north European waters, and most of this section is taken up with the description of the Selachii (sharks) and the Blatoidei (skates and rays). The low salinity of the Baltic bars the presence of elasmobranchs except as occasional visitors, therefore nearly all the species recorded are from the North Sea area and several of these are very rare, such as the electric and eagle rays and some of the sharks On the other hand, certain rays, such as Raia clavata in the North Sea, the Skager Rack, and Cattegat, and Raia batis with a wider range, have here their maximum distribution, whilst the cosmopolitan Acanthias vulgaris is the commonest doglish and is to be seen in swarms in the North Atlantic Sharks and rays feed upon Sharks and rays feed upon almo t all the groups in the animal kingdom—fishes of all sorts, molluses, crustacea, echinoderms, annelids, and even sea-anemones and ctenophores, Selache maxima, the basking shark, being entirely a plankton feeder, eating small crustacea and even diatoms. Good notes are given on the feeding and breeding habits of all known forms.

Japanese Pliocene Mollusca—The molluscan fauna of the lower part of the Kakegawa (Lower Phocene) Series in the province of Tôtôrm forms the subject of a monograph by Jirô Makiyama (Mem. Coll Sci. Kyoto Imp. Univ., ser. B, vol. 3). The beds in question, Dainitian, occur between Hutamata and Minamiyama on the Tôkaidô, or East Sea Road, and seem referable to the Plaisancian. The fauna contains 171 species of which 46-8 per cent. are known as living Detailed descriptions of these, including many new species, are given and accompanied by six excellent plates.

PEAT AS A SOURCE OF WAX—The curious metabolism of peat plants, which releases large quantities of fatty substances, and impresses very characteristic structural features on the plant form, was investigated a few years ago by Priestley and Hinchliff (see The Naturalist. 1922, p. 263, and 1924, p. 201). These fatty, by-products are now being turned to commercial account. In the current issue of the Bulletin of the Imperial Institute (vol. 25, No. 3) an account is given of some experiments which have been carried on there on the extraction of wax from some samples of peat from Chatham Islands. The work follows on similar researches already carried out in Germany

Hot extractions made in a Soxhlet apparatus with chloroform as a solvent gave the remarkably high yield of 25 per cent. of crude wax, the yield in the case of most peats so far tested being from 6 to 8 per cent. The cost of chloroform, however, prohibits the use of this method as a commercial venture. Other experiments showed that benzene or mixtures of benzene and alcohol were almost as efficient for extracting wax from the peat, besides showing considerable advantage in regard to cost Preliminary trials indicated that kerosene might possibly be used, but its high boiling point made the subsequent separation of the wax difficult. The crude wax had a dark colour, a melting point from  $70^\circ$  to  $74^\circ$  C, and could not readily be It is estimated that a market could be bleached. found for 500-2000 tons of the wax per annum for use in boot polish and related industries. An analysis of the peat remaining after extraction of the wax showed that the residue would form a useful fuel

SMALL ELECTRIC FURNACES FOR THE LABORATORY.—The Chemiker-Zeitung of Sept. 28 contains a description of a new type of small electric furnace, with which a crucible can be heated in one hour to a temperature of about 860° C. The furnace is most easily adapted to a tension of 110 volts, and if the current does not exceed 2.2 to 2.4 amperes the heating coils will last for several thousand hours. The furnaces are made by the firm Hugo Helberger, of Munich, and are provided with specially adapted regulating resistances, by means of which it is easily possible to control the temperature.

The Weathering of Textile Fibres — The Chemiker-Zeitung for Oct 8 contains an account by Dr. H. Sommer of experiments on the weathering of textile fibres, carried out on the roof of the observatory at Neubabelsberg, near Potsdam. The complete record of the investigation will be found in the Leipz. Monatschrift fur Textilindustrie. It has been found that the weathering is chiefly a surface effect produced mainly by ultra-violet rays and is helped, particularly in the case of wool, by the presence of moisture. Of the different materials examined, silk proved to be the least and wool the most resistant to the disintegrating action of sunshine. The sunshine-hours required to produce comparable effects were as follows: silk, below 200; jute, 400, artificial silk, 900; cotton, 940; flax, 990, hemp, 1100, raw wool, 1120; chromed wool, about 1900; but differences in thickness were not taken into account.

The Carbon Arc—The issue of the Physikalische Zeitschrift for Sept. I contains a paper by Drs R. Seeliger and H. Schmick, of the University of Greifswald, on the mechanism of the carbon arc. By the use of an arc enclosed in a vessel, they have been able to study the effects of reducing the air pressure from atmospheric to 2 or 3 cm. of mercury, on the positive crater and the light it emits, and on the volt-ampere characteristic of the arc. They find that in air and in nitrogen, the area of the crater increases, and the current per unit area of the crater therefore decreases as the pressure decreases. The increase of area of the crater is accompanied by a decrease of its temperature and a decrease of the voltage between the carbons. If the decrease of pressure is slow, at 1 or 2 cm. of mercury, the pressure rises from below 40 to 50 or 60 volts, and at about 0 5 cm. of mercury falls suddenly to 32 volts, at which it remains steady, the crater being much reduced in area. No theory of the arc has been propounded which will account for the facts observed.

## The New School of Biochemistry at Oxford.

THOUGH the study of chemical physiology in Oxford began some three hundred years ago, it is only within the last few years that this subject has been recognised as a separate school of science. It then became clear that the importance of the study of the chemistry of living things together with the rapid extension of knowledge in this field made it imperative that recognition should be given to biochemistry by the foundation of a readership or chair. The University was fortunate in the generosity of Mr. Whitley, of Trinity College, who made possible the foundation of a chair, thenceforward known as the Whitley Chair of Biochemistry. To this chair was elected, in 1920, Dr. Benjamin Moore, who may be regarded not only as the first to hold the chair of

were opened by the Rt Hon. Viscount Cave, Chancellor of the University, on Oct 21, biochemistry ceases to be taught in the premises of the Department of Physiology, and this Department therefore gains valuable extra accommodation. It has, however, been an important feature of the development to keep the Departments of Physiology and Biochemistry in intimate connexion with one another. In order to accomplish this, the new building is L shaped and forms with the old Department of Physiology part of a quadrangle. There has also been incorporated in the scheme of development a conjoint library and a conjoint large lecture room. The buildings are turther connected by passages upon two floors, a great convenience for students.

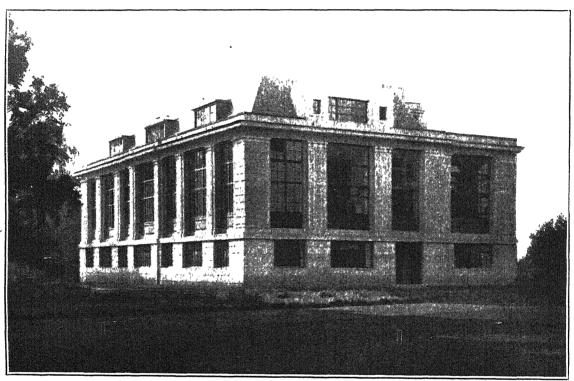

FIG 1 .- School of Biochemistry University of Oxford.

biochemistry at Oxford, but also as among the pioneers of biochemistry in Great Britain. Unfortunately for Oxford, Moore did not live long to enjoy his new The present holder of the chair, Dr. Rudolph A. Peters, was elected towards the beginning of 1923. Shortly after he came to Oxford, the University received from the Rockefeller Foundation an offer of £75,000 towards the erection of a new Department of Biochemistry. £55,000 of this was to be devoted to the building and its equipment, and the remaining £20,000 towards maintenance. This offer was accompanied by the condition that the University should guarantee to contribute the sum of £25,000 or its equivalent in annual income towards the general maintenance of the new Department. This munificent gift was gratefully accepted by the University Not only did it provide for a proper development of biochemistry, but also it solved the acute problem of providing additional accommodation for the Department of Physiology, a need that had been long delayed.

By the possession of these new buildings, which

No. 3026, Vol. 120]

The building has been designed by Mr. H. Redforn and is built in a classical order, which was made necessary by the need for large windows and therefore narrow wall spaces between them. It consists of three floors and a mezzanine floor. Upon the ground floor are found, besides the usual offices, the conjoint lecture theatre capable of holding some two hundred persons, cold storage, a dark room for photographic work, and one for physical work. There are also a workshop and preparation room, and a small room for nutrition work upon rats The first floor, which may be styled the teaching floor, is connected by through passage with the Department of Physiology. It consists of two large class rooms built side by side and capable of accommodating about one hundred students at a time. They can be used either as one room or two. In addition to the class rooms there are students' balance room, a polarimeter room, and a demonstration lecture theatre. The upper or second floor is reached through a mezzanine floor made possible by the height of the class rooms. Upon this floor is to be found a rest room, a room for constant temperature work, a research room with roof lighting, and the entrance to the indoor animal house. The second floor is entirely devoted to investigation. Besides a professor's research suite and other research rooms, there is also a sterilising room, a small bath room, an operating suite, an outdoor laboratory, and an aquarium room. This floor opens direct to a flat roof

With regard to the fittings, gas, water, and electric power have been brought into all rooms, and a trough system has been adopted for the drainage of water. Using this in conjunction with movable tables and cupboards designed upon a unit system, it will be possible for each research worker to arrange the benches to suit the particular investigation upon which he is engaged.

Subject to any unforeseen development, the present

building should satisfy in the main the needs of biochemistry in the University for the present. Smaller wants are not yet, however, adequately met. There is, for example, the question of the research library, for which separate endowment is required. The modest sum of £2000–£3000 would go far to provide what is required in this direction. The most serious want of all, however, is believed to be that of providing studentships to enable the better men to stay behind for a period of one to two years to obtain training in research work, and so obtain the fullest possible use of the scientific opportunities of the University. This is a need which the Department of Biochemistry shales with other scientific departments, and until it is properly met there is no doubt that Great Britain will not make the best possible use of the brains of the younger generation at the University.

## The University of Birmingham.

NEW BIOLOGICAL BUILDINGS.

WITH the progress of the biological sciences, both methods and needs have changed. The laboratories and apparatus of a generation ago are no longer adequate even for teaching purposes, still less for research. At Birmingham the three cognate Departments of Botany, Zoology, Brewing and Biochemistry of Fermentation have long been inadequately housed in the older part of the University in Edmund Street. This session, however, they have moved to their new quarters at Edgbaston. The new biological block was formally opened on Oct. 20 by the Prime Minister, Mr. Stanley Baldwin.

The buildings, the site and general character of which form part of the original design of Sir Aston Webb, face University Road, being situated between the Chemical Department and the Harding Library. The total cost of buildings and equipment is upwards of £120,000, towards which Sir William Waters Butler, Bart, has generously contributed £40,000,

and an anonymous donor £5000.

Zoology occupies the ground floor of the new block, brewing and biochemistry of fermentation the greater part of the first floor, and botany the second floor, with certain rooms also on the first floor. A large lecture theatre, shared by all three departments, each of which also has its own lecture room, forms a third floor.

One important development is the recognition of the principle of departmental libraries. Each of the three departments in the new block has its own separate library, in which will be housed nearly all the periodicals and books dealing with the three subjects respectively. These departmental libraries will be under the general supervision of the University Librarian and the Library Committee.

The three departments have already started work in the new buildings, although the internal equipment and furnishing is not yet complete. The following

accounts deal with the new departments.

#### ZOOLOGY.

The new Zoological Department, which forms the ground floor of the biological block, has been constructed on a spacious scale. There are three teaching laboratories, for elementary, for advanced, and for post-graduate honours students respectively. The laboratories have ample accommodation, good lighting, both daylight and artificial illumination, and modern fittings. The Department possesses a small lecture theatre for advanced teaching, while the zoologists, botanists and biochemists between them share a large theatre. This lecture theatre accom-

modates the large elementary class, the greater proportion of whom are medical students.

Original research is as much the raison d'être of a university scientific department as is teaching. For the purposes of research the new department is admirably equipped. The apparatus includes not only the microscopes and microtomes of the classical zoological laboratory, but also the numerous and often elaborate apparatus used in the newer experimental developments of the science. The members of the staff have each a private room fitted out as a laboratory. There is a research laboratory for other original investigators working in the department, with a special room for entomologists, dark rooms, an animal room, a tank room, etc.

The Department has a distinguished past record. Prof. T. W. Bridge, one of the original professors at Mason College, Birmingham, carried out much valuable research work on fishes. His successor, the late Prof. F. W. Gamble, is known to zoologists all over the world for his researches on the colour changes in crustaceans and for his study of the remarkable composite organism Convoluta, a planarian worm with symbiotic algæ. The late Prof. Leonard Doncaster was a member of the staff when he did his epoch-making work on sex-inheritance in the moth Abraxas grossulariata. Mr. H. G. Newth, the present senior lecturer, is an embryologist who has made a number of important original investigations. Incidentally, a large share in the design of the laboratories and fittings falls to his credit. The present head of the Department is Prof. H. Munro Fox.

## Brewing and Biochemistry.

The British School of Malting and Brewing and Department of Biochemistry of Fermentation was founded at an earlier date than the incorporation of the University of Birmingham. Accordingly, at first, it was a department of Mason University College. The School was formally declared open by Mr. H. Cosmo O. Bonsor, on Jan. 18, 1900. The late Prof. Adrian Brown had been appointed, and held the position until his death in 1919, the School being maintained during that interval by contributions from the brewing industry. After the death of Prof. Brown, a further appeal was made to the brewing industry, with the result that a full endowment was provided for the chair, to which the name of Adrian Brown is attached.

The Department consists of a series of sixteen rooms running from east to west. There is a spacious general laboratory, a well-appointed microscope room,

and a research laboratory. The professor and the lecturer have each a private room and a laboratory assigned to them, and there is a special laboratory for analysis, and incubator room and dark rooms for

photography and polarimetric work.

One of the objects of the School is to advance research in the many fields open to investigation in connexion with the fermentation industries, and the professor possesses wide powers with regard to aiding the investigations of competent workers by finding accommodation in his laboratories, and in other ways Applications concerning such questions should be made to the professor direct

Prof Adrian Brown's research work is well known. It dealt with studies on micro-organisms—bacteria and yeasts—and the products of their action on different substances. He studied specially alcoholic fermentation, and made many notable contributions to the chemistry of enzymes. The high reputation of the Department for training and research built up by the late Prof Adrian Brown has been well maintained during the eight years which have clapsed

since his death.

#### BOTANY.

The new Botanical Department, comprising some thirty-three rooms, occupies the second floor of the new block, as well as the eastern portion of the first floor. On the first floor are sterilising and incubating rooms for mycological work, staff and preparation rooms, and the herbarium. The latter contains a number of important collections, being particularly rich in cryptogams.

The eastern end of the second or mam floor is designed chiefly (though not exclusively) for teaching purposes, and the western end for research. Between these two parts, conveniently placed for both, are the departmental library, museum, store rooms, etc. So far as possible, laboratories and staff and other rooms in which microscope work is carried on, have been

arranged on the north side of the building

Special provision has been made for the study of plant physiology. The physiological laboratory is a large, well-lighted room at the extreme eastern end of the department. It extends across the entire width of the building, being provided with north and south windows as well as three large roof-lights. Adjacent to this laboratory are a small chemical laboratory and a physiological dark room. For experiments in which open air is necessary, a working bench- of concrete and lead has been erected on the roof. This bench, like the ordinary laboratory benches, is provided with water, gas, and electric current, and communicates with the physiological laboratory below.

In addition to the building and its fittings, a considerable sum of money has been set aside for apparatus. It may therefore be claimed that the new Botanical Department is well equipped and thoroughly up-to-date. In particular, the facilities

for research have been vastly improved.

### THE PRIME MINISTER'S TRIBUTE.

The new buildings were formally opened by the Prime Minister at a special congregation in which the Chancellor (Viscount Cecil of Chelwood) conferred upon Mr. Baldwin the honorary degree of LL.D. The choice of Mr. Baldwin was singularly appropriate, for not only is he a Midlander, but he was also at one time a student at Mason College, and the University of Birmingham can thus claim that it is the only provincial university which has a Prime Minister on its register of students. The function was in every way a success, and the Prime Minister, in proposing the toast of "The University" at the luncheon which

followed, made an eloquent and impressive speech. He thought that few developments in Great Britain were more full of hope than the development of the modern universities, a development of modern times which would be looked on by the historians of the future as the genuine renaissance of the nineteenth; and twentieth centuries—a renaissance as genuine and as pregnant in its hopes for the future as the renaissance of the fifteenth century. "You have to go back about a century to see the first roots of this movement. At that time Oxford and Cambridge were more or less monastic institutions in which learning was preserved, with some skill, in cold About that time you begin to see the rise storage of the literary and philosophical societies, in cities like Manchester and Birmingham pre-emmently. They were societies on which (as with all good movements) much scorn was poured in their own day. Quarterly and Edinburgh Reviews, which stood then for the highest forms of culture, used to denounce them on the ground that they encouraged the vice which has always been a favourite vice in Birmingham -they complained that they showed an exclusive fondness for speculation on the constitution of matter -no uninteresting of unimportant subject

It was not until the last half of the nineteenth century that the university movement began to gather strength, and in Birmingham it was associated with the wonderful activity of Joseph Chamberlain and his fellow-workers, who showed what enlightened municipal government could do. When the University of Birmingham obtained its charter, mainly through the energy of Joseph Chamberlain, the magnetic personality of that statesman secured the necessary financial support. But he passed away, and, not long after, the War came; and the University went

through difficult times.

Financial help was needed. Recent Governments had done what they could, the City of Biriningham gave £15,000 a year, and the surrounding district about £4000. Vast fortunes are not so common in the Midlands as in some other parts of the country, but that did not make it any more difficult for co-operative effort to raise money. "We are probably standing at the beginning of one of the periods of mereasing knowledge which will mark more than ever that renaissance of which I spoke. The transformation of the world is proceeding apace; the civilisation of the west is overflowing into the east, and the dead east is giving itself up from the sandhills of the desert; and the human panorama, more vivid and more extended than ever, is rolling itself out before our eyes m a way which would have filled our parents with amazement. So in science the problems of power and space, of the atom and the electron, are being attacked and invaded with more vigour and more success than at any time in the past. This work is being done by the co-operative effort of mon m a thousand colleges, such as this, all over the world. We cannot live on the sacrifices of those who have gone before. A double duty lies before us of maintainmg the work which they began, and pushing forward mto realms of which they had no conception . . . I believe that in time the people of this country will learn to realise that the teachers in these universities are the helpers and servants and the friends of humanity. And when once that essential truth has been grasped, there will be no doubt then that all the help that you need in material matters will be forthcoming."

In the afternoon the Prime Minister went to Chancellor's Hall to open the new wing of the hall of residence for men students (built through the generosity of Sir Charles Hyde), where he insisted on the value of corporate life in a university education.

## The Imperial Agricultural Research Conference.

A NUMBER of valuable reports and memoranda have been drawn up and circulated to delegates of the Impenial Agricultural Research Conference for their information and consideration. We print below some notes on points raised in these memoranda.

#### AGRICULTURAL OFFICERS OVERSEAS.

The recruitment in Great Britam for the agricultural services overseas has always been a matter of difficulty. Appointments were formerly few and irregular, and no arrangements were made to prepare men for them, with the result that, for many years, these services were more or less dependent on the flotsam and jetsam of English schools, that is, those who had not made good in Great Britam. Recruitment began to improve with the present century, in the establishment by Mr. Chamberlam of the West Indian service, and by Lord Curzon of the much larger one in India. Latterly, first India and then Egypt have closed their doors to the purely agricultural candidates, although they still appear to require scientific 'experts' in commexion with agriculture

The finding of suitable men for the Colonial service was rapidly becoming an impossible task, when the Empire Cotton Growing Corporation started its career, with the creation of a number of attractive studentships in Great Britain, with the idea of providing a sort of pool of specially trained men, from which candidates could be drawn, when needed, for pushing the growth of cotton in British dependencies. When appointed, these men were attached to the local agricultural departments The Colonial Office followed suit, and similar scholarships have been given for several years A leaflet has now been placed in the hands of the delegates of the Imperial Agricultural Research Conference advertising the creation, among others, of sixteen to eighteen post-graduate scholarships "annually, at any rate till 1933 inclusive," by the Colonial Office, and twelve studentships by the Empire Cotton Growing Corporation for the current year. The difficulty in recruitment may now be regarded as solved, in that a career is opened up for any promising student who qualifies himself in any branch of science connected with agriculture

Among the questions which have been discussed at the Conference is that of the position of scientific officers in agricultural departments and their relation to the administrative staff. Two memoranda on this subject have been submitted from Tanganyika. It is pointed out that the agricultural departments in the older tropical colonies have usually evolved from botanic gardens, to the staffs of which have been added a chemist, an entomologist, a mycologist, and m some cases a geneticist and an agricultural economist. The chemist frequently has his attention diverted from agricultural matters by demands for his services as an analyst or toxicologist, and the biological officers can rarely give adequate time to research owing to the amount of advisory work which they are expected to undertake. It is urged that the primary work of a technical officer should be that of an observer and investigator, and that his opportunities for travelling should be increased, to enable him to keep in close touch with the executive agricultural officers in the various districts, and the problems actually arising in the field. These officers, and the owners of plantations and farms who are willing to do so, should be invited to make observations on definite lines laid down by him, and thus increase the thoroughness of his investigations.

To enable such a policy to be carried out, it would

be necessary to supply the technical officers with assistants who could carry on work at headquarters while they were travelling, and also to prepare technical memoranda for use in advisory work by executive officers. A memorandum from New Zealand on the same subject indicates that the adoption of such a policy in that Dominion has proved very valuable.

# Information Bureaux on Indian and Colonial Agriculture.

The English public is not much interested in what goes on in India, unless perchance some Rajah visits England or there is a recrudescence of Hindu-Mohammedan religious nots The main employment of the people, agriculture, is scarcely ever referred to in the daily Press, and, indeed, it would be looked upon as a very dull and uninteresting subject. But it is not really so, if properly presented, and it must be confessed that writers on scientific subjects are sometimes not very lucid. This point of view is stressed by the chief agricultural officer in India in introducing the report which he has prepared for the Conference. Starting at home, he asks for a publicity officer for the Indian Agricultural Department, to popularise the work being done for all classes in the country. He goes a good deal further, and pleads for a closer haison between all parts of the Empire for the same purpose; India and the tropical colonies on one hand, and the torrid zone and temperate regions on the other In short, he suggests the establishment of a publicity bureau in London, to act as a popular clearing house of the results of agricultural research within the Empire a very different thing, of course, from the publicity section of the Empire Marketing Board The natives of most of our African Colonies grow crops similar to those in India, and largely under like conditions of climate. The hundred folio pages of this report on the present position of agricultural research in India, prepared by the heads of the various sections, on crops and their treatment, agricultural practices, cattle and all veterinary matters, should prove extremely useful to the officers engaged in trying to improve the undeveloped agriculture of our African Colonies

One of the greatest difficulties in the study of agriculture in the British dependencies overseas lies in the matter of literature. The whole range of crops in the warmer parts are different from those in Great Britain, and text-books, except on certain individual crops, are practically non-existent. The literature, therefore, consists of journals and pamphlets in London, it is often a matter of considerable difficulty to locate a particular pamphlet or report, although there are important collections in various places. The Colonial and India Offices both contain a considerable number of journals and pamphlets on agricultural subjects, but these appear to be primarily intended as official records, and are not arranged for the convenience of the occasional visitor. Imperial Institute and Kew Gardens have also accumulated a large amount of material, and this is admirably arranged for study; while the Bureaux of Entomology and Mycology will have all the information required in their respective subjects.

There are also scattered collections of less importance, and the London agencies of different countries are generally willing to supply copies of such pamphlets as they have for distribution. But there is a rather urgent need for strengthening one of these centres, or creating a new one, where the student of any

crop or practice of country may, without undue labour, find all that he wants. This subject is presumably being explored by the Colonial Office, and if the publicity bureau for India advocated above is established, this bureau will in the natural course of events be located where such a library is formed. Attention to this subject has been directed by the circulation of a leaflet describing the Science Library in South Kensington, where some quarter of a million 'references' have been got together on 'Agriculture, Economic Botany, and Forestry.'

The difficulties experienced in the collection of information as to the agricultural research going on in the different parts of the overseas Empire had to be faced by the Organising Committee of the Imperial Agricultural Research Conference The Dominions, including India, are large enough to employ a numerous and well-organised staff, and it is never a difficult matter to obtain excellent summaries of progress being made year by year. But this is not the case with the colonies, varying as they do from countries the size of France to a few minute and povertystricken oceanic islands; and it was a happy inspiration which led the Marketing Board, with the help of the Colonial Office, to circularise the various British colonies in the tropics, asking them to prepare and forward by a certain date summanes of the present position of agricultural research in them and the most pressing needs for its increase in their territorities One can imagine the interest which this circular must have caused in some of them, the ready response, and the incentive to make as brave a show as possible for submission to the collective authority of the Imperial

A summary of these reports has been prepared by the Organising Committee in handy form and printed under the title "Agricultural Research in the Overseas Empire": and a copy has been placed before each member of the Conterence Canada, Australia, New Zealand, the Union of South Africa, and the Irish Free State lead off with some 56 pages; and, with the exception of a couple of pages on Cyprus and Palestine, the rest of the 120 pages are generously devoted to tropical colonies, concluding with a note on the activities of the Empire Cotton Growing Corporation in various parts of the Empire. This pamphlet should be a veritable godsend to the student of British tropical agriculture, a subject hitherto overshadowed by the often excellent literature so freely dispensed by Java, Cuba, Porto Rico, Hawan, and the Philip-

As a kind of addendum to the summary of reports referred to above, a series of extracts have been issued in folio form, typed and bound, each dealing with a separate aspect of agricultural research in the tropics (it is obvious that it would be impossible for members of the Conference to go through the originals in the short time at their disposal in Great Britain). One of these "Memoranda" deals, for example, with "Crops and Plant Breeding," and includes extracts of special interest at the present time Such are: Breeding as applied to long-term crops, such as cacao, coffee, palms, tea and rubber, which occupy the ground for many years; shifting cultivation and its replacement—a system under which isolated areas of bush or forest are felled and burnt, and for a year or two food crops are grown, after which the land is allowed to become jungle again; the effect of grass and wild plants or cover crops on long-term plants; the problems requiring investigation in West African cacao, which is grown as a forest by the natives over large areas, without any attention to ordinary agricultural practice; the problems connected with Burma rice, the main source of this cereal food in the

British Isles, the effect of soil and climate on the quality of Nyasaland tobacco, from which country the bulk of our "Empire tobacco" comes; the efforts being now made to evolve new kinds of banana on account of the spread of the 'Panama disease' (the cultivated bananas do not usually form seed and are always reproduced for crop purposes by suckers, on the same principle as the sugar cane and our potatoes); while the concluding third of this memorandum of 47 pages refers exclusively to various problems which are met with in the Empire cane sugar industry, now severely threatened by the fiscal support given in almost all foreign countries in the tropics to their own sugar factories. Various other crops are merely mentioned at the end of the memorandum, including sisal hemp, coconuts, oil palms, and so on; and to this list is added the question of industrial alcohol, now of special importance because the production of petrol in the British Empire is so very small.

# INVESTIGATIONS AIDED BY THE MINISTRY OF AGRICULTURE.

The Ministry of Agriculture has issued for the use of the Conference two valuable publications describing the research work in agricultural science conducted at institutions in receipt of grants from the Ministry. The investigations deal with practically every important branch of agricultural science, and although conducted at many different centres, show little or no evidence either of overlapping or of lack of co-ordination. Only a few items can be selected for comment.

The question of the necessity for change of seed m potatoes is under investigation. The practice of employing seed produced under more rigorous climatic conditions is almost invariably adopted in England, and is supposed to prevent 'physiological degeneration', however, no evidence of the superiority of yield of Scotch seed over home-grown seed has yet been obtained in careful tests over several consecutive years, provided the crop be kept free. of virus disease. Although the yields of crops are more effected by season than by any other factors, a dull summer, such as the past one, is not necessarily associated with a low yield, as would at first sight be expected. In studies of barley one reason for this has been elucidated. In dull light the leaf surface is larger but less active in rate of food production than in bright light, so that the plant maintains a fair level of activity over widely variable weather conditions. Methods of statistical inquiry have been developed to deal with the data obtained from the field experiments, and their applications to results from the long-time Rothamsted experiments have brought to light previously obscure factors influencing the yield, thus enabling direct experimental tests to be undertaken. Besides climatic factors, variations m the soil conditions, even within a small area, affect the yield; the so-called 'even' crop of the farmer, if harvested and weighed in small plots, is in reality very uneven. Soil heterogeneity includes variations in physical, chemical, and biological characteristics. The latter two can only be shown at present by laboratory examination of numerous samples from the area in question, but the former is susceptible to rapid demonstration by measurements with a dynamometer of the soil resistance to a cultivation implement.

In the realm of animal husbandry, the famous permanent pastures of British agriculture have come under critical examination. The presence of wild white clover has been regarded as the essential characteristic of a good fatting pasture, and the earlier work was largely devoted to the encouragement.

of leguminous plants by phosphatic manures, and basis slag in particular, with striking results wards it was shown that the effects were only observed to their full extent on originally poor grass land and under fairly high rainfall Recently, the necessity for clover as an appreciable constituent of the herbage has been questioned. The work originated in Germany and has been actively taken up in Great Britain. It is claimed that by frequent applications of quick-acting artifical nitrogenous fertilisers, and by close stocking, a constant supply of young grass herbage is secured, which in both feeding value and amount is much greater than can be obtained by the older methods, thus enabling more head of stock per acre to be kept Investigation is being made of certain technical difficulties that may arise, such as the effect of periods of drought, the prevention of rankness in the herbage due to the animal excreta, and the possibility of the soil becoming sticky or poached in wet periods by the treading of the animals

A closely allied line of investigation is the examination of the inineral content of pastures. It has been found, especially in certain overseas regions, that serious diseases among stock are associated with a deficiency in the pasture of some essential element, e g. rodine, normally present only in minute amounts. The study of these deficiency diseases, and the methods of remedying them, either by manuring the grazing area or by direct supply in supplementary rations of the missing ingredients, has necessitated the co-operative investigation of pathologists, chemists, and agronomists. This illustration of team-work among different investigators—and different institutions—is only one of many others to be found in the researches conducted with the financial assistance of the Ministry of Agriculture.

#### EMPIRE SOIL PROBLEMS

Memorandum 8, issued by the Organising Committee of the Conference, contains the technical , papers relating to soils and manures, which are up for discussion. Almost the whole field of pedological work is touched upon, though very naturally problems relating to tropical soils form a large proportion of The Parliamentary Under-Secretary for the Colonies points out our ignorance with regard to tropical soils and the important chemical and physical problems arising in connexion with irrigation and soil deterioration. The extensive and intensive methods of carrying out a soil survey are dealt with by Sir John Russell, who emphasises the need for standardisation of methods and for more general agreement as to the determinations which shall be carried out.

Practically all the Dominions and Colonies represented submit accounts of the work being carried out by them and the special difficulties and problems with which they are faced From West Africa, as a result of a previous conference between neighbouring colonies, comes the request for the establishment of a Bureau of Soil Science the duties of which shall be the collection and collating of the results of soil investigations, the publication of approved methods of soil classification and analysis, and the provision of the machinery for assisting colonial agricultural chemists to carry on soil research to a point beyond

that possible in their local laboratories.

As might well be expected, the assistance which soil survey work can give to irrigation problems comes out in several of the memoranda. Australia and the Union of South Africa both pay attention to the types of soil and the composition of the water suitable for irrigation, and the latter Dominion has some further interesting notes on exhaustion of soil by pine-apple

cultivation The Barbados review their own special soil problems connected with the sugar cane, whilst Ceylon discusses soil erosion, and Nyasaland the soil problems of tobacco growing. Altogether the memorandum presents a useful survey of Empire soil problems and will repay perusal by workers in Great Britain

#### STORAGE AND TRANSPORT OF AGRICULTURAL PRODUCE.

Matters of outstanding importance relating to the preservation and transport of agricultural produce, and in particular of perishable fruits of Australia, New Zealand, and South Africa, were discussed at the Conference. It has been pointed out that if the problems of immigration and land settlement are satisfactorily settled, the total production of foodstuffs from British colonies can be greatly increased. At the present moment, only some five per cent. of fruit produced in Australia is exported, while for New Zealand and South Africa the successful marketing of perishable food-stuffs, produced in great quantity, is still exceedingly difficult.

It is matter for congratulation for all concerned that arrangements have been made for Dr. Franklin Kidd, of the British Food Investigation Board, to visit Australia for the survey of local problems, the investigation work already in progress, and the possibilities of further work. It is anticipated that on the evidence of his report extensive lines of new in-

vestigation will be initiated

The cluef problems of transport for Australia relate to frozen lamb, mutton, beef, poultry, rabbits, and fruit, all of which present considerable difficulty. is well known, for example, that the time taken on the voyage from Australia to England is, in general, too long to enable the export of chilled beef to be commercially feasible; that this fact has for long been a serious handicap to the Australian cattle raising industry, and that owing to low prices realised for frozen materials, the ordinary method of freezing does not provide a way out of the difficulty. Much will depend on the matter of Dr. Kidd's report, as it is clear that improvements are called for in the pickling of meat, the treatment of slaughter-house wastes, and the defrosting of beef Regarding fruit, much valuable information is now available relating to brownheart in apples, the atmospheric and temperature conditions existing in ships' holds carrying apples from Australia, the storage properties of Victorian varieties of apples, and the incidence of the conditions known as 'bitter bit,' 'scald,' and 'internal breakdown'. The experience acquired in the investigation of such matters should be of infinite value when the problems of preservation and transport of oranges, pears, peaches, apricots, grapes, and tomatoes have been more fully assailed.

The problem of apple storage for New Zealand is also one of prime importance. The main damage to exported fruit is due to 'brown heart,' while in local storage there is extensive 'flesh-collapse' due to low storage temperature combined with high humidity. It is gratifying to note that improvements in storage have been assured and are further prefigured by the reduction in the water-content of apples. It cannot yet be said that the preservation of pears is satisfactory, but much practical success has followed storage at comparatively low temperatures. It has been shown that orchard conditions greatly affect the ability of the fruit to withstand bad storage conditions, and that in certain cases prematurity of the fruit tends to occur with extreme susceptibility to 'flesh-collapse.' It is hoped that this difficulty may be overcome by storage under relatively high temperatures and low humidity. It would further appear

that increasing the water-holding capacity of soils on which prematurity regularly occurs may enhance the resistance of fruit to 'flesh-collapse,' and that on such soils green manuring is decidedly advantageous.

In a paper to the Conference communicated by Dr. E. A. Griffiths, Government Physicist of the Department of Agriculture of South Africa, it was pointed out that it is neither practical nor sound to carry out investigations on fruit in England when such fruit has already undergone a period of long transport. On the other hand, the Dominions have neither the personnel of research workers nor the facilities for the conduct of the essential work urged that extensive investigation in England would help mainly to the understanding of the influence of respiration products on the storage of fruit and in the improving of technical methods in determining the conditions and effects of storage.

## AGRICULTURAL ECONOMICS.

In a paper presented to the Conference on "Research in Economics for Tropical Countries," it was pointed out that since the raising of crops is the main industry in tropical countries, research must be carried out in agricultural economics planters turn out partly manufactured produce, eg. sugar, coffee, or sisal, and are thus confronted by a twofold problem. At present more attention is usually paid to the economics of the factory than to agricultural economics, and thus the gain in the factory is largely discounted by loss in the field. When profits are good, work is often uneconomically performed, and thus when bad years come it is difficult to prevent disaster. In such cases the action necessary depends on the nature of the crop, though the general aim must be to control the quantity of produce reaching the market, e.g. coffee valorisation and rubber production restriction.

In the tropics, methods of research—which must be concerned largely with cost accounting-are usually simpler than in temperate climates, as it is usual to farm one main crop only and that generally for export. Research in agricultural economics is necessary, and should be a public charge To provide information, an agricultural census, the co-operation of planters, and the provision of agricultural colleges are required, while the formation of agricultural accounting societies like those at present under trial

m Wiltshire might be beneficial.

In a memorandum by Mr. W. J. Lamont, Chief of the Division of Agricultural Economics and Marketing, Union of South Africa, consideration was urged of a scheme to provide statistics and other information required by agriculturists seeking new outlets for their products. Lack of such information has been frequently felt, as, for example, when a South African commission was inquiring into the possibility of

increasing wine exports.

Some system is required whereby Britain and the Dominions may be provided with the latest available information about custom duties, trade agreements, restrictions on imports, and statistics of exports and imports, etc. Publication might be undertaken by the Empire Marketing Board or the Board of Trade Journal, with perhaps special supplements dealing with a different Dominion each month Probably the best method would be to issue a special annual volume with monthly or quarterly supplements. If an annual volume were published, a few special articles might be included on such subjects as the Canadian and American wheat pools, the compulsory pooling of tobacco in the Union of South Africa, or the wine trade of the British Dominions. In conclusion, Mr. Lamont urged that the adoption of some

such scheme would be of the greatest service to all the Dominions

SUGGESTIONS FOR CO-OPERATIVE RESEARCH.

In a comprehensive memorandum on "Co-operation m Agricultural Research," prepared for the Con-, ference by R W. Thornton, Director of Field and Animal Husbandry in the Union of South Africa, the following are among the subjects suggested as suitable for research on co-operative lines in various parts of the Empire (a) The farming of Angora goats for the production of mohair, an industry which has seriously declined in recent years, (b) the relative cost and efficiency of horse versus mechanical transport for various farm purposes; (c) 'rust' m wheat, the principal factor limiting the production of this most important crop; (d) the production of legumes, particularly the soya bean, which could be grown in rotation with maize and might be produced in equal quantity in those parts of the Empire where maize is largely grown, (e) the ocean transportation of live-stock and agricultural products with the view of greater uniformity in regulations.

## University and Educational Intelligence.

Bristol — The opening of the new physics laboratory by Sir Ernest Rutherford on Oct. 21 was marked by a notable address by him on the significance of fundamental research and the splendid facilities which the laboratory affords for its pursuit. "Under such excellent conditions," he remarked, "we may confidently anticipate that this laboratory will fulfil the wishes of the donor by developing into one of our most important centres of training and What is now needed is the endowment of a number of research fellowships of about £250 a year each, to enable young men or women who have shown marked ability for research to carry out investigations in the laboratory.

At a special congregation held in the great hall of the University on Oct. 21, Prof. A. M. Tyndall, Henry Overton Wills professor of physics in the University, presented to the Chancellor, Lord Haldane, the following distinguished men of science for the honorary degree of doctor of science: Prof. Max Born, professor of theoretical physics, Gottingen; Sir William Bragg, director and Fullerian professor of the Royal Institution; Prof. A. S. Eddington, Plumian professor of astronomy, University of Cambridge; Prof. A. Fowler, Yarrow professor of the Royal Society; Prof P. Langevin, professor of general and experimental physics, College de France, Paris; and Sir Ernest Rutherford, Cavendish professor of experimental physics, University of Cambridge, and president of the Royal Society.

CAMBRIDGE.—It is announced that Sir Arthur Shipley bequeathed some of his library to the Molteno Institute, the Balfour Library, and the Cambridge Philosophical Society.

Mr. F. R. Parrington, Sidney Sussex College, has been appointed Assistant to the Superintendent of the Museum of Zoology.

A grant of £150 has been made from the Worts Fund on the recommendation of the Polar Research Institute committee to the recent Cambridge expedition to Edge Island, Spitsbergen.

Mr. Norman McLean, fellow and tutor of Christ's College, and University lecturer in Aramaic, has been elected master of the College in succession to the late Sir Arthur Shipley.

LEEDS —The University Council has placed on record its grateful indebtedness to Sir Edward Allen

Brotherton, Bart., for his munificent generosity towards the University The New Library Building, to be called 'The Brotherton Library,' will link the name of Sir Edward Brotherton inseparably with the history of the University. An offer by Messrs. Briggs, Son and Company to provide funds for a Scholarship of £150 a year, tenable in the Mining Department for a period of five years, has been gratefully accepted.

LONDON.—The following doctorates have been conferred by the Senate · D Sc. in chemistry—Mr. J. W. Baker, an internal student of the Imperial College (Royal College of Science), for a Thesis entitled "A Correlation of the Effect of Certain Groups on the Reactivity of Aliphatic and Homocyclic Substitution." D.Sc in physics—Mr. R E. Gibbs, an internal student of University College, for a thesis entitled (1) "The Variation with Temperature of the Intensity of Reflection of X-rays from Quartz and its Bearing on Crystal Structure", (2) "The Structure of a-Quartz"; (3) "The Polymorphism of Silicon Dioxide and the Structure of Tridymite"; (4) "An X-ray Investigation of the Lower Members of the Fatty Acid Series". D.Sc (engineering)—Mr. G W Burley, an external student, for a thesis entitled "An Investigation into the Temperatures and Thermal Quantities involved in Lathe Turning Operations on Plain Carbon Steel," and other papers

The Gow Lectures on the "Colloid Chemistry of the Rubber Industry" will be given, in English, by Dr E A. Hauser, of Frankfurt-on-Main, at University College, at 5 15 on Nov. 7, 9, 11, 14, 16, and 18 Free lectures on "Statistical Mechanics Old and New" will be given by Mr. R. H. Fowler, at the Imperial College of Science and Technology, on Nov. 10 and 24 and Dec. 8, at 5.45. No tickets will be required in either case

ONFORD—On Friday, Oct 21, the Rockefeller School of Biochemistry, described elsewhere in this issue, was opened by Viscount Cave, the Chancellor of the University, in the presence of a large gathering which assembled in the Sheldoman Theatre to hear the Chancellor's address, and afterwards accompanied him to the fine new building in the Parks in which the School is housed. The Vice-Chancellor (Dr. Pember, Warden of All Souls'), in accepting the gift on the part of the University, gave expression to the gratitude due to the generosity of the Rockefeller Trust, and to the anticipation of the great results that might be expected to follow from the splendidly equipped department under the charge of the Whitley professor, Prot. R A Peters.

Dr. Gilbert Bourne, of Merton College, has been reappointed an elector to the Linacre professorship of zoology and comparative anatomy. Mr. David Murray-Rust has been appointed lecturer in natural science at Balliol College.

According to the report of the Institute of Agricultural Engineering for 1926 which has just been presented to congregation, the principal work of the institute was in connection with the desiccation process for producing sugar from beet. The work on sub-soiling has been continued.

It is announced that the postponed fifth Pan-American Child Congress, referred to in our issue of April 16, p. 583, will be held at Havana, Cuba, beginning on Dec 7, next.

PROF. MAX PLANCK, the well-known professor of physics of the University of Berlin, is retiring after forty years' service. He will be succeeded by Dr. Erwin Schrödinger, of the University of Zurich.

## Calendar of Discovery and Invention.

October 30, 1786.—So early as 1780, Galvani made experiments on muscular contractions due to electric Pursuing his studies in 1786 with his nephew Camillo Galvani, in September of that year it was observed that these contractions could be brought about by the use of metals touching the nerves. The experiments with the exact dates are preserved in a paper in Galvani's handwriting, "Esperimenti circa l' Elettricità dei metalli"; and the results were formally drawn up in a Latin dissertation of 62 pages, bearing the date Oct. 30, 1786, forming the substance of the most important section of his "Commentary on the Electric Forces .." published five years later but differing from it in some important particulars.

October 31, 1896.—Thrrty-one years ago, on Oct. 31, 1896, Prof. Kamerlingh Onnes communicated to the Royal Academy of Sciences, Amsterdam, a paper by Dr. Zeeman "on the influence of magnetisation on the nature of the light emitted by a substance. Pursuing a hint given by Faraday, several experiments were tried. The principle was this, the light of the electric arc being sent through a heated tube containing sodium vapour, is analysed by a Rowland's grating. The tube is placed between the poles of an electro-magnet. When acted on by the magnet, a slight broadening of the two sodium lines is seen, tending to show that forced vibrations are produced m the atoms by the action of magnetism ' (see Nature, Dec. 24, 1896, p. 192)

November 1, 1895—The first experiments with a

cmematograph in Germany were made by the photographer, Max Skladanowsky, on Nov. 1, 1895, in the Wintergarden at Berlin.

November 4, 1745.—It was the attempt to electrify water in a phial which led to the invention of the Leyden jar, an invention which Sir John Leslie described as constituting an epoch in the annals of science. The discovery was made by Ewald Jürgen von Kleist at Cammin, Pomerania, and by him communicated to the German physicist Lieberkuhn on Nov. 4, 1745. The experiments were immediately repeated by Cuneus and Lallemand at Leyden and described by Musschenbroeck. Von Kleist was a president of the high court of justice, and the house he lived in at Cammin bears an inscription to the memory. He was born on June 10, 1700, and died on Dec. 10, 1748.

November 4, 1847.—The use of anæsthetics began with the discovery of the action of nitrous oxide by Davy, but a new era in surgery was ushered in by the work of Morton, at Boston, Mass., in 1846, with sulphuric ether, the news of which led to Simpson's experiments. Late on the evening of Nov. 4, 1847, Simpson and his friends Keith and Duncan sat down to the hazardous experiments in Simpson's diningroom, which resulted in the discovery of the value of chloroform. "With each tumbler newly charged, the mhalers resumed their vacation" They became hilarious, bright-eyed, loquacious, "but suddenly there was a talk of sounds-louder and louder-a

moment more, then all was quiet, and then a crash."

November 4, 1869.—Founded by Sir Norman
Lockyer, Nature first appeared on Nov. 4, 1869. Writing in the Jubilee number, M Deslandres said. "During its existence the journal has ably recorded the magnificent discoveries which have distinguished the last fifty years in every branch of science . . . and it has been the better able to present them to the public because the founder has himself been one of the foremost builders of this noble edifice"

## Societies and Academies.

#### LONDON.

Optical Society, Oct. 13-L. C. Martin: Experiments in ultra-violet refractometry. The experiments described have for their object the application of critical angle methods for the refractometry of liquids in the ultra-violet. A thin film of liquid can be held between two quartz hemispheres which are traversed centrally by an approximately parallel beam; the film receives the radiation at the varying angles of incidence resulting on rotation of the system. In this way, analysing the transmitted radiation with the aid of a quartz spectrograph, the critical angles for definite wave-lengths are measured, from which refractive indices can be calculated. The procedure necessary in seeking precise results is discussed, and a series of measurements on glycerine-water mixtures likely to be useful for immersion fluids in ultra-violet microscopy is given A set of interesting phenomena of the extinction bands is described and explained —Guy Barr. The construction of wave-length scales for spectrograms A method is described by which an approximate scale of wave-lengths may be projected geometrically from a uniformly divided scale on to a spectrogram whereon a sufficient number of lines have been identified to enable constants of a Hartmann interpolation formula to be derived. Such a scale is of value in assisting the recognition of other lines between which accurate interpolation may be required.

#### ROME.

Royal Academy of the Linces, June 1.—A. Lo Thermionic balance.-L. Rolla and G. Piccardi: Ionisation potential of terbium. By comparison with sodium and calcium, the ionisation potential of terbium is found to be 6.74 volts. This value talls into place on the portion of the ionisation potential curve characteristic of the rare earths, and furnishes further confirmation of the conclusion that, in the rare earth group, such potential increases with the atomic number.—A. Angeli and B. Bigiavi . The two p-nitroazoxybenzenes. When treated with bromine in the presence of a small amount of iron filmgs, the two p-nitroazoxybenzenes behave differently, the isomeride melting at 148° yielding a tribromo-compound, and that melting at 152° a monobromo-derivative.—G Bruni and E. Geiger: New derivatives of caoutchouc. The action of nitrosobenzene and other nitroso-compounds on caoutchouc in benzene solution or on the latex of Hevea brasiliensis in pyridine solution results in the formation of compounds termed nitrones. These do not react with hydroxylamine, but with phenylhydrazine the nitrone of isocaoutchouc yields the phenylhydrazone of a ketone which contains the carbonyl in the caoutchouc chain.—F. Zambonini and S. Restaino: Double sulphates of rare earth metals and alkalı metals. (8) Double sulphates of cerium (cerous) and sodium. The compounds  $Ce_2(SO_4)_3$ ,  $Na_2SO_4$ ,  $2H_2O$  and  $4Ce_2(SO_4)_3$ , 5  $Na_2SO_4$ ,  $8H_2O$  are described.—F. Zambonini and A. Stolfi: Double sulphates of rare earth metals and alkali metals. (10) Sulphates of neodymium and ammonium. Under the various experimental conditions employed, only the compound  $Nd_2(SO_4)_3$ ,  $(NH_4)_2SO_4$ ,  $8H_2O$  could be detected.—L. Cambi: The diazohydrates. The available facts concerning the structure of the alkali salts of the normal diazohydrates are in no way contradictory to the structural formula attributed to the hydrates by Angeli, but do not agree with Hantzsch's view of this structure -L. De

Marchi. The origin of the thermal waters of Montegrotto - B. Morpurgo: The influence of manition on homoplastic grafting. -C. Rosati: The permutable correspondences for an algebraic curve.—L. Laboccetta: A general method for replacing an inequality and a limitation by an equation, and its use m analytical geometry. E. Pin: Investigation of the primitive function for functions of several variables. - G. Thomsen: The kinematics of rigid bodies in general relativity .-- A. Masotti: Dynamic action which a perfect liquid exercises on a solid eylinder, of any section, movable of itself.-F. Sbrana Plane motions of an incompressible fluid in which the lines of flow are isotachic. -G B. A new variable star. -F. Neri: Certain Lacchini properties and applications of the neon lamp. Observations on the relationship between the effective ignition voltage for a neon lamp under alternating current and the frequency of the current indicate that the phenomenon of ignition requires a certain time and that the ignition of one electrode is profoundly influenced by the state of ionisation in which the medium has been left by the other. - ({ Charrier: Organic compounds of quinquevalent bismuth. In hydrochloric acid solution, bismuth trichloride reacts with aryldiazonium chlorides to form stable crystalline compounds which contain quinquevalent bismuth and in which the chlorine atoms are readily replaceable by sulphure or intric residues. G. Malquori Hydrates of aluminium nitrates. From the cryohydre point for the system,  $Al(NO_3)_3 \cdot Il_2O$ , namely, -27°, to 73° 5, at which temperature the monohydrate melts, the only compound in equilibrium with the saturated solution is Al(NO<sub>3</sub>), 911,0. At higher temperatures, the solubility curve exhibits marked discontinuity, corresponding with the existence of two hydrates poorer in water and the octo-and the hexa-hydrate. -- V. Caghoti and A. Stolfi: Double sulphates of bismuth with the alkalı metals. (1) Sulphates of bismuth and potassium. Investigation of the system,  $\mathrm{Bi_2(SO_4)_3} - \mathrm{K_2SO_4} - \mathrm{H_2O}$ , indicates the existence of the compound  $\mathrm{Bi_2(SO_4)_3}$ ,  $3\mathrm{K_2SO_4}$  but not that of  $\mathrm{KBi(SO_4)_2}$ .—Remo de Fazi: Alcoholic fermentation of solutions of glucose in water exposed to radiations from a moreury vapour lamp. Exposure of water to the radiation from a quartz mercury vapour lamp results in increase of the velocity of fermentation of a solution of glucose in the water.—A. Cavinato: Dehydration of anophyllite.—E. Remotti: Assumption of vitellin during the embryonic development of the fowl. -B. de Finetti: Conservation and diffusion of Mondelian characters. (1) Panmittic case —M. Muccioli Astringent juice of the fruit of the bitter Diospyros kaki and its application in China and Japan as an impregnating material for paper and wood.

### BRUSSELS.

Royal Academy of Belgium, April 2. -The following grants were made from the Potter Foundation; W. Conrad (2000 franes) to assist him in the pursuit of his researches on the Belgian fresh water flagellates; J. Pasteels (500 francs) for the study, at Wimereux, of the cyto-physiological action of the dilution of sea water on the eggs of lamellibranchs; the "Jardin expérimental Jean Massart" (5000 francs) for the continuation of experiments in plant physiology commenced by the late Jean Massart; Edg. Zunz (6000 francs) for the purchase of apparatus necessary for his researches on the regulation of glycæmia by the method of pancreatico-jugular anastomosis; Th. De Donder (7500 francs) for assisting in the publication of a work on the theory of integral invariants; Gilta (1000 francs) for the execution of

plates 'relating to chemical crystalligraphy.—Paul Stroobant: The work on stellar and planetary photography of the Royal Observatory (Uccle)—Fred. Swarts Trifluordimethylketone. This is readily obtained by heating trifluoracetylacetic ester with 10 per cent. sulphuric acid under a reflux condenser. the products being the above ketone, alcohol, and carbon dioxide. Details of its chemical and physical properties are given—J E. Verschaffelt. The physical signification of the second fundamental law of thermo-dynamics.—Th De Donder The signification and generalisation of Schrodinger's equation.—
The De Donder and G Van Lerberghe: The invariantive theory of waves—R Moens and A Juliard. Some chemical reactions in the gaseous phase in high frequency electro-magnetic fields. The gases studied were submitted to high frequency (wave-length about 100 metres) in tubes without electrodes, initial pressure about 12mm Hydrogen and oxygen combined totally in less than a second, ammonia was produced from hydrogen and nitrogen No reaction was observed with a mixture of hydrogen and carbon monoxide or oxygen and nitrogen -T. Van Hove: Some researches on the direct introduction of substituents in the aiomatic mercaptans -L Van den Berghe · Preliminary note on the stimulation of the cardiac tissue of fishes by momentary extensions — J Guillissen . A mode of application of Tammann's method of thermal analysis to the study of reactions between solid phases. To increase the sensitiveness of the method the use of the nime-temperature curve has been replaced by the curve temperature-difference of temperatures, using the double galvanometer of Le Chatelier-Saladin. The reaction temperatures of the following mixtures have been determined by this method: lead oxide-copper sulphate, lead oxidemolybdic anhydride, ferric oxide-barium carbonate, ferric oxide-baryta, ferric oxide-calcium carbonate. -J Guillissen and Richard: The temperature of formation of zinc ferrite starting from the solid constituents

May 3 -P. Stroobant: An account of the work done by the National Committee of Astronomy during the year 1926 -- Seligmann and Maury: The geodesic work of the Institut cartographique militaire in 1926 -Paul Levy. Classical logic. Brouwerian logic and mixed logic -Louis Giltay: The discovery of a species of Gobius, new to Belgium (Gobius pictus) and on the ethological conditions of its habitat.

#### SYDNEY.

Royal Society of New South Wales, Sept 7.—A. R. Penfold and F. R. Morrison. The essential oils of *Eucalyptus micrantha* and *E. hæmastoma*, part i. The principal constituents were found to be. E. hæmastoma: Eudesmol, sesquiterpenes (aromadendrene and probably eudesmene), d-a-pinene, cincol (10-15 per cent.) with a very small quantity of phellandrene. E. micrantha I-a-phellandrene. sesquiterpenes, terpineol and piperitol and their Caproic acid esters, d-a-pinene, cineol (less than 10 per cent.), with sesquiterpene alcohols and traces of the aromatic aldehydes. Piperitone, if present, did not exceed 5 per cent. in quantity. Solid eudesmol, a characteristic and constant constituent of the oil of E hamastoma, was found only in the oil obtained from Hill Top; altitude has a considerable bearing upon the production of this solid sesquiterpene alcohol. The presence of solid eudesmol in the coastal material of *E. hæmastoma* and the nondetection of phellandrene in the crude oils by the B.P. test, offered a ready means of distinguishing the oils from that of E. micrantha.

## Empire Cotton Supply and Needs.

THE Lancashire cotton industry is, as is well known, in a somewhat parlous condition, and one important factor involved is that it has not control over its supplies of raw material. About one-third is grown in Egypt and South America, and two-thirds are from the United States; but the cotton of these two sections is so different that two separate industries deal with it in Lancashire. The first appears to be fairly prosperous, but the larger industry, dependent on the United States supply, is in trouble. This supply fluctuates enormously, and demands from elsewhere are increasing rapidly. During the past five years the crop has varied from 11 to 18 million bales. cotton mills are springing up in many countries, and those in America alone now require about half the crop These figures indicate sufficiently how precarious is the position of the bulk of the Lancashire cotton mills

This state of affairs has, however, been long predicted; and more than twenty years ago a British Cotton Growing Association was formed, to encourage growing American cotton within the Empire, chiefly by assistance in marketing the produce Since the War, matters have become acute; and about five years ago a much more ambitious scheme was launched, namely, the Empire Cotton Growing Corporation, which sought to stimulate the mill owners to united action, by a levy of 6d. on each bale of cotton entering Great Britain. When the participation of a large proportion of the mill owners was secured, the Government endowed the movement with close on one million pounds, saved through the control of the Egyptian cotton during the War, and an Act of Parliament was passed sanctioning the levy for five years. This period is now terminating; and the Lancashire industry concerned is about to be sounded as to whether the levy should be continued.

It will be of interest to note how this Corporation, mainly composed of business men, has set about its task. A central office was opened in London, a library collected, and an excellent quarterly journal started. Senior officers were sent on surveys of various parts of Africa, India, and Australia, and their reports have been freely circulated. In Africa the transport problem dominates, and large sums of money have been spent on improving communications. In India a large model estate has been assisted and financed in the Punjab, for the encouragement of growing American cotton; and in Australia £3000 a year has been given for five years for founding cotton stations.

The most interesting point, however, is the appreciation of the Corporation of the need for scientific work A central Research Institute has been built in Trinidad, and the local College liberally subsidised. A number of post-graduate scholarships have been given on a generous scale to encourage recruitment, and four research institutions in Great Britain have received £1000 a year for five years, to assist in training these men Senior officers, largely with Indian cotton experience, were engaged to start the work in the colonies, and the trained men have been drafted out in succession In the circumstances, judging by the annual reports now coming in, progress has been remarkably rapid, although it is recognised that it will be many years before the goal is reached—of making the Empire self-sufficient as to its cotton requirements to be hoped that the Lancashire mill owners will vote for a further five-year period of the levy. The ball has been set rolling, but there are many obstacles in its path; and the co-operation of this powerful and broad-minded Corporation cannot be overestimated. C. A. B.

## Biology and Birth-Control.

 University of London: Galton Laboratory for National Eugenics. Eugenics Lecture Series, 14. The Right of the Unborn Child; being a Lecture delivered on November 1.3, 1999, to Teachers from the London County Council Schools. By Karl Pearson. Pp. 26+3 plates (London: Cambridge University Press, 1927.) 3s. net.

(2) Contraception (Birth Control), its Theory, History, and Practice: a Manual for the Medical and Legal Professions. By Dr. Marie Carmichael Stopes. New and enlarged edition. Pp. xxvi + 480 + 5 plates. (London: John Bale, Sons and Danielsson, Ltd., 1927.) 15s. net

THE two works which are the subjects of this review both arrive at the conclusion that birth-control is a necessity, but whereas Prof. Karl Pearson desires it in the interests of the future generation, Dr Marie Stopes demands it in order to relieve the over-harassed mother.

(1) Prof. Karl Pearson's pamphlet is a reprint of a lecture delivered to elementary school teachers; we congratulate him heartily on his descent from the clouds of the higher statistics, and his determination to talk plain common sense which every one can understand. He shows in the most convincing manner that certain repulsive deformities like 'lobster-claw,' and certain dangerous weaknesses like hæmophilia or bleeding, are handed on from

generation to generation, he says that in a primitive state of society individuals afflicted with these taints would never have been allowed to survive, much less to marry. He points out that such weaklings are only preserved in the mawkish at measurements of sentimental sympathy which is developed in our civilisation, and that in the history of humanity advance has come not from the persistence of old civilisations, but from the irruption of virile races reared in 'a hard cradle' who had overwhelmed the effemmate civilisations which they encountered and appropriated as much of their culture as they saw fit.

Prof. Pearson is less happy in his remarks on the relation of religion to eugenies It is true, as he says, that the biological function of religion is to assure the solidarity of the tribe, and that the powerful taboos of primitive religion concerned themselves largely with the three great events in human life-birth, marriage, and death. thinks, with the late Sir Francis Galton, that eugenic principles will never prevail until they have behind them the driving force of religious sentiment, he calls therefore for a modification of religious sanctions which will make the marriage of those marred with physical and mental defect to be as great an offence against religion as murder and adultery, unless those so married consent to have no children Prof Pearson, however, forgets that primitive man obeyed the taboos not so much from r' fear of his fellow-tribesmen as from dread of the supernatural intervention of the higher powers in whom he fervently believed From Prof Pearson's contemptuous remarks about God it is clear that he does not share this belief, and without it religious sentiments are impossible. The idealistic and highminded may have regard to the interests of the race when their individual interests collide with them, though personally we doubt it, but the hope that the lazy and self-indulgent will pay any attention to the interests of posterity, if to use an American's phrase 'they can get away with it,' is idle. Least of all will they be deterred by a make-believe religious sentiment if they have ceased to believe m God

While in general we agree with Prof. Pearson's views, certain difficulties occur to us. Hæmophiha, for example, manifests itself in men but is transmitted through women. Now could we seriously expect a healthy, vigorous young woman to abstain from marriage with an equally healthy young man because her great-great-grandfather had suffered from hæmophiha and she might be a transmitter of the taint? Again, whilst we cordially

would be a great gain, these defectives ate at the worst a small percentage of the dation: the really great menace comes from an over-propagation of the idle and thriftless, who would not be classed as either physically or mentally defective. To support the children of this class the thrifty are taxed to the bone. The birth endowment for which Prof. Pearson calls is already in full action in this case; it seems to us that the compulsory sterilisation of the thriftless when they bring into the world more children than they can support, would do more for society than the segregation of defectives

(27 \(\beta\): Marie Stopes's book consists in a history of the various varieties of birth-control and especially of contraception. She recalls to our memory the fact emphasised by Prof. Carr-Saunders that birth-control in the form of infanticide and abortion has been practised by all races of men since time immemorial, and that even drugs which prevented conception were known in antiquity useful service in demolishing the legend, sedulously propagated by a certain coterie, that the legality of birth-control was established by Bradlaugh's fight for it She shows convincingly that the very pamphlet in connexion with which Bradlaugh was prosecuted had been sold for years without let or hmdrance, and that the police only interfered when the publisher added to it several indecent illustrations. Bradlaugh's intervention, so far from helping the cause of birth-control, really hindered it, since it caused it to be associated in the minds of the public with his unpopular atheistic views

Dr. Stopes seems to think that Carr-Saunders has disposed of the arguments of Malthus. Never was there a greater illusion—Malthus's main position stands to-day as an impregnable rock, and has indeed since Darwin's time become a commonplace of biology. The fact that Malthus did not foresee the expansion of our food-supply by the exploitation of then undiscovered agricultural areas is irrelevant, this merely postpones for a limited time the advent of the crisis which he predicted and which has already arrived in overpopulated countries like India and China.

Dr. Stopes gives an elaborated and detailed account of the physiology of sexual intercourse and of the relation to it of the various methods of birth-control now in use, giving of course prominence to that which she recommends. It would be entirely out of place to discuss these methods in the columns of NATURE, but Dr. Stopes raises several points of considerable physiological interest which may be

She maintains that the male mentioned here sexual discharge, in addition to the fertilising spermatozoa, contains a hormone the absorption of which is most beneficial to a woman's health. A priori this seems not unlikely, but it is an exceedingly difficult matter to prove, and when one views the healthy, vigorous unmarried women around one, it is rather difficult to believe Then Dr. Stopes stresses the fact that in the emotions accompanying contion, there is a female crisis which is reached later than the male crisis, and that when this is not attained the woman is left in an unsatisfied and irritated condition which, often repeated, leads to marital unhappiness and makes a shipwreck of the marriage.

Whilst the normal reader must experience a shock in finding these intimate matters discussed m such detail and in such plam language by a woman, and whilst the reviewer must admit that he sympathises with this feeling of shock, there are certain considerations which give him pause before he indulges in condemnation of the author Some years ago, in the common-room of a certain college, the reviewer happened to be the only biologist present when one of Dr. Stopes's books ("Married Love ") was discussed. He was immediately challenged to give his opinion on it, and he replied that while it seemed to him that this book could only have been written by a person entirely devoid of reticence, yet that it would do good in giving information about physiological matters such as the female crisis, which could be obtained nowhere else. To his amazement and stupefaction, two of his questioners, both scientific men and both married, confessed an utter ignorance of the very existence of a female crisis!

Dr. Stopes gives figures to show that the chances of survival of the children decrease with the rapidity of succession of pregnancies, and the cases selected from her records give ample evidence of the fearful wreckage of women's health which results from overbearing. Part of the book is given up to incisive replies to the various attacks which have been made on Dr. Stopes, and the reviewer must confess that in these replies she has his entire sympathy. When the urgent necessity of birth-control by some method is becoming evident not only to biologists but also to economists and even to politicians, it can only be described as hypocrisy on the part of the Church to condemn practicable methods and recommend abstinence and selfcontrol to the ordinary man in the street who lives with his family in cramped quarters. That there is inherent wickedness in the sexual process itself is a superstition worthy only of the darkest Middle Ages and reflecting an outlook on the world which no rational man can now uphold

In conclusion, we can only say that Dr Stopes's book is a compendium of most valuable theoretical and practical information on the all-important subject of birth-control E W. MacBride

## A Treasury of Learning.

Introduction to the History of Science By George Sarton Vol. 1 From Homer to Omar Khayyam (Published for the Carnegie Institution of Washington Publication No. 376) Pp xi +839 (Baltimore, Md Williams and Wilkins Co, 1927.) 10 dollars.

CONFRONTED with this volume, for which the only adjective at all appropriate is 'colossal,' one can appreciate the feelings of the rustics before Goldsmith's schoolmaster:

"And still they gaz'd, and still the wonder grew That one small head could carry all he knew."

Dr. Sarton's amazing erudition, equalled only by his energy, is fittingly accompanied by a breadth of sympathy and interests due in part to his personal history, of which he gives some details A Belgian by birth, of mixed French and Flemish ancestry, he married an Englishwoman and has since become American by adoption. His work on the history of science was begun near Ghent, but on the outbreak of war in 1914 he was forced to abandon his home and to bury all his manuscripts in the garden. Fortunately, the invader overlooked this buried treasure, and the papers were safely recovered in 1919 mind's eye, the vision of Dr. Sarton digging up buried knowledge from its hiding-place is symbolic, for he has devoted his whole life to this very task, and the first-fruits of his labours are now presented to us.

'First-fruits' may seem a particularly mept word to describe the book now before us, which many a scholar would be more than content to have to his credit as the sole product of his working years. Yet to its author it is but the foundation-stone of an imposing building the plan of which he sketches as follows There are to be altogether three series of books. The first series will consist of a purely chronological survey of the history of science (a term which, as interpreted by Dr. Sarton, has a wide significance), from the earliest times to the present day, in units of half a century. The present volume is the first of this series, and

seven or eight more of the same size re The second series will give surveys of types of civilisation and will run to about The third series will deal with volumes evolution of special sciences, in eight or pine volumes, namely, (1) logic and mathematics; (2) physical sciences, (3) biological sciences; (4) sciences of the earth, (5) anthropological and historical sciences, (6) medical sciences; (7) edicational sciences; (8) philosophy, and (9) general index Of this vast field, Dr. Sarton hopes himself to cover the first series down through the eighteenth century, parts of the second series dealing with Semitic and Far Eastern civilisations, and the second volume of the third series. If this ambitions, programme is realised, as every one will hope it may be, Dr. Mellor will have to look to his laurels! Not content with his linguistic attainments, Dr Sarton light-heartedly undertook, as a mere trifle in passing, the study of Arabic under Prof J R. Jewett and Dr. D. B Macdonald "there were giants in the earth in those days"

The chronological survey in this introductor volume begins with the dawn of Greek and Hebre knowledge in the ninth and eighth centuries BC and ends with the time of Omar Khayyam (second half of eleventh century A.D.). Each half-century from the fourth century B.C. onwards, is given a separate chapter and is christened with the name of its most representative man; thus 250-200 B.C. is called "The Time of Archimedes," while A D 800-850 bears the name of the mathematician Al-Khwārizmī. This simple device is remarkably efficient in helping the memory to assimilate the chronological sequence, and its adoption must be regarded as a stroke of genius. Especially for medieval times, our memory of dates is too often lamentably vague, and yet we must acquire an adequate sense of the succession of men and events if our mental pictures of the progress of science are to be accurate Dr. Sarton rightly insists upon the essential importance of strict chronology, so far as it can be ascertained, and has chosen his chapter titles for mnemonic purposes; "we should find it difficult," he justly says, "to remember that such or such a man flourished in the first half of the ninth century, and such or such another in the second half of the same century, but we can more easily recall that the former flourished at about the same time as Al-Khwārizmī, while the other will naturally cling in our memory to the personality of Al-Rāzī" It has seemed necessary to dwell upon this point, because a casual glance at the book might give the impression that it is

solely a work of reference, whereas in point of fact it contains much to be read and remembered

Each section is provided with a brief introduction or summary and a critical review of the relevant literature. The wealth of bibliographical detail is frankly stupendous, and in those sections which we have tested, very little of real importance has been omitted, though we noticed, for example, that H. Joachim's article on "Aristotle's Conception of Chemical Combination" was not mentioned in the list of authorities quoted in the paragraph on Aristotelian chemistry. Such occasional lapses are inevitable, and serve merely to throw into higher relief the sound and careful scholarship and painstaking industry which Dr Sarton has brought to bear upon his researches.

Of especial value are those sections devoted to Chinese science Hitherto, information respecting the scientific attainments of this people has been very difficult to collect, and even when collected its value and trustworthiness could not always be properly estimated. It is probable that a fuller knowledge of early Chinese work would cause us radically to modify some of our present opinions on the development of the sciences—particularly chemistry, as urged by Prof Partington-and a systematic survey of the subject is urgently required. Dr Sarton has provided an excellent starting-point in his collation and valuation of the critical literature available, and perhaps European or Oriental scholars may now be stimulated to undertake the necessary labour. It seems certain that such labour would be well repaid

Similar care has been bestowed upon the accounts of Muslim science, about which more is known, but of which there has been no comprehensive synthesis, most investigators having chosen particular topics for intensive study rather than a broad survey of all the various aspects. Dr. Sarton gives us the materials for such a survey and has pointed out the salient features. He has also taken pains to transliterate proper names accurately, a merit which is conspicuous by its absence in most histories of science, and the lack of which is not merely provoking but often seriously misleading.

The history of politics and that of art have been deliberately omitted on the ground that these subjects have already been adequately treated by others. Prehistoric times are also omitted for the present, since the rapid advance of archæology in recent years suggests that a short postponement may enable a much more satisfactory account to be given later.

Dr. Sarton expresses the hope that his sketch No. 3027, Vol. 120]

of the vast panorama of two thousand years of intellectual progress may help to guide the activity of a large number of scholars, by allowing them to undertake special investigations of particular topics without losing a sense of proportion and perspective. That his hope will be realised cannot be doubted, but we believe he will do more than prevent a loss of sense of perspective: he will convey it to those who have never possessed it and will render applicable to the history of science the words of the Pervigilium Veneris.

"Cras amet qui nunquam amavit; Quique amavit cras amet."

E J. HOLMYARD.

#### Modern Astronomy.

Astronomy A Revision of Young's Manual of Astronomy By Dr. Henry Norris Russell, Dr. Raymond Smith Dugan, and Dr. John Quincy Stewart Vol 1: The Solar System Pp xi+470+xxi Vol 2: Astrophysics and Stellar Astronomy. Pp xii+471-932+xxx. (Boston, New York, Chicago and London: Ginn and Co, 1926-1927) 2.48 dollars each vol.

THIS much-anticipated book is described as a revision of Young's "Manual of Astronomy," although, as stated in the preface, "the scope of the new work is somewhat more extensive than that of the former 'Manual,' and intermediate between this and the 'General Astronomy.'" The classical works of Young have long been the best volumes of their kind, except for the fact that they have been out-of-date on the physical side, and no more appropriate task could have been undertaken by their illustrious author's successors at Princeton than that which they have now brought to fulfil-So numerous and radical have been the ment advances of the last few decades that it has been found necessary practically to re-write the book, with an inevitable increase in length. The result, it may be said at once, is worthy of its prototype.

The two volumes deal respectively with "The Solar System" and "Astrophysics." This is probably the most satisfactory method of dividing the subject of astronomy for treatment as a whole, although the more minute classification given in the introduction to the book is inconsistent with it, in the sense that it is impossible to assign each of the six branches mentioned therein definitely to either the solar system or astrophysics. No method of dividing and subdividing astronomy is entirely satisfactory, for astronomy deals with a universe and not a multiverse, and the science has

progressed far enough for that fact to emerge and confound the would-be analyst. The present cleavage into two volumes cannot evade a number of phenomena—notably the sun, which it has to split into two parts. In the first volume the treatment of this body is mainly descriptive, it is chiefly an account of the sun as seen through the telescope. The second volume deals with the examination of the sun by the spectroscope and bolometer.

The contents of the first volume may be summarised as follows. After a brief introduction, astronomical systems of measurement are described, leading up to astronomical instruments and the problems of practical astronomy. The earth, moon, and sun are then discussed, with a separate chapter on eclipses. Between the consideration of "the planets in general" and the separate consideration of individual planets, a chapter of 49 pages, on celestial mechanics, is inter-The final chapter deals with comets and polated meteors and the origin of the solar system. Volume 2 begins with a chapter on the analysis of light, after which the solar spectrum and the sun's light and heat are dealt with. A chapter on atomic theory and astrophysics makes possible a general consideration of the stars and their various characteristics, including double and variable stars. Then follows a discussion of star clusters, the milky way, and the nebulæ, and the work concludes with two chapters on the constitution and evolution of the stars An appendix to each volume contains useful data, and each chapter includes a number of exercises for the student.

It is intended that the first volume shall be mastered before the second is approached—a plan which "has been adopted as a result of many years' experience in lecturing" It is with diffidence that one ventures to question the conclusion of the distinguished authors on this matter, but it should perhaps be said that the reviewer has found it more satisfactory to introduce all the principles and instruments of investigation before dealing with the bodies to which they are applied. In the treatment here adopted the spectroscope and its applications are not introduced until the second volume is reached, with the result that the accounts of several phenomena, begun in the first volume, have to be completed in the second. Perhaps no general rule can be laid down in the matter, and in any case both volumes are available together for the teacher to deal with as he pleases.

The treatment is comprehensive, clear, and, needless to say, accurate. The book is suitable for

the beginner with only an elementary knowledge of physics and mathematics, but includes, nevertheless, a little mathematical work (printed in smaller type) in the astrophysics volume which the elementary student is invited to omit use of the calculus has been completely avoided. The book appears to us to be undoubtedly the best text-book of general astronomy now available. The only criticism of a general character which we can make is that there are occasional lapses in English, of which two examples, taken from volume 1, will be sufficient. On p. 53 we read: "In the coelostat the plane of the mirror is parallel to that of the polar axis." The words "that of" should, obviously, be removed Again, on p. 164, a paragraph is headed "Method of Determining the Size of the Moon's Orbit, that is, its Distance and Parallax." The distance and parallax dealt with are, of course, the moon's, not those of its orbit. We have, however, noticed no serious ambiguity arising from this cause

The book is clearly printed and well and copiously illustrated, although the reproduction (Fig. 190) of Sir Norman Lockyer's flash spectrum, obtained in India in 1898, is very disappointing.

H. D.

## Our Bookshelf.

Pernicious Anæmia, Leucæmia, and Aplastic Anæmia: an Investigation from the Comparative Pathology and Embryological Point of View. By Dr. J. P. McGowan. Pp. vii + 116 + 5 plates. (London: H. K Lewis and Co., Ltd., 1926.) 7s. 6d. net.

Dr. McGowan's investigation of these blood diseases originated from a series of observations on leucosis in fowls and iron deficiency as it occurs in pigs. The similarity between the former condition and the pernicious anæmia-myelogenous leucæmia group of diseases in human beings was apparent, and it was considered that their common association with iron deficiency in morbid conditions of the hæmatopoietic system might shed light on some of the problems of human blood disease. Commencing with the demonstration of leucosis as a definite pathological syndrome with several different causal factors, it is postulated that the similar syndrome in human beings has likewise a fundamental pathogenesis. It is considered that this is a modified hyperplasia due to an irritative condition and ending in some cases in sclerosis or aplasia of the bone-marrow. In those cases of pernicious anæmia in which no definite irritative factor, such as tapeworm or specific poison, is recognised, it is suggested that there has been some general infection which has damaged the bone-marrow.

The association with iron deficiency is through

the metabolic function of the liver in preparing iron and fat for the production of erythrocytes. The aplastic form of anæmia has its cause in the failure of the poisoned liver to carry out this 'function, apart from the toxic changes in the bonemarrow. Iron deficiency is considered to be due to deficiency in milk of iron relative to protein or growth-stimulating substance and to the growth potential of the young animal.

The whole subject is presented with unusual lucidity, and Dr. McGowan's conclusions will be of considerable interest to students of pathology

and comparative medicine.

The Commerce of Agriculture · a Survey of Agricultural Resources By Prof F. A. Buechel (The Wiley Agricultural Series) Pp ix +439. (New York John Wiley and Sons, Inc; London: Chapman and Hall, Ltd., 1926.) 18s. 6d. net.

The framework of this book is ambitious. agricultural resources of every part of the globe are explored, with, in some cases, disappointing brevity. Under 'resources,' aspects are considered which do not, as a rule, find a place in agricultural text-books For example, there are sections on climate, soils, origin and development of trade, agricultural organisation, and so forth. The matter is so encyclopædic that a considered review is not possible here As a test we turned to the section on 'Rice,' and would query the accuracy of the statement that "rice is by far the most important crop" in India Again, under the heading of potato diseases it is disappointing to find that only two are mentioned, 'scab' and 'blight.' The botanical names should have been given, for, under the latter, two, 'early' blight and 'late' blight, are mentioned as if they were distinct diseases, whereas both, presumably, are Phytophthora infestans.

These criticisms should not, perhaps, detract from the real value of the book, which under one cover presents a really informative survey of world agriculture. We commend in particular the excellent statistical maps showing crop distribution in various countries, selected from the admirable

series published by the US. Government.

The Credibility of Herodotus' Account of Egypt in the Light of the Egyptian Monuments: being a Lecture delivered at the Fifty-fifth Congress of German Philologists and Schoolmasters at Erlangen. By Wilhelm Spiegelberg. With a few Additional Notes by the Translator, Aylward M. Blackman. Pp. iv +40+2 plates. (Oxford: Basil Blackwell, 1927.) 2s. 6d. net.

A TRANSLATION of Prof. Spiegelberg's lecture on the credibility of Herodotus as a recorder of Egyptian history will doubtless be welcome to many whose acquaintance with the language of the original is limited. Much of what he has to say is new, while his intimate acquaintance with the monuments has enabled him to give greater precision to views already put forward in general terms on the sources of the information recorded by the 'father of history.' His approach to the

problem is by way of two inquiries. First, what was the state of Egyptian civilisation at the time Herodotus visited the country? Secondly, in what circles of society did he move during his visit? His conclusion is that the intense preoccupation of the Egyptians in their own past had produced a number of popular actiological legends evoked by the monuments, and that these were related to Herodotus by interpreters and members of the inferior ranks of the priesthood. The application of this theory to the story of the escape of Sesostris from the fire over the bodies of his two sons is certainly ingenious and more than probably correct.

Wave Mechanics: an Introductory Sketch. By H. F. Biggs. Pp. 77. (London: Oxford University Press, 1927.) 4s. 6d net.

Mr Biggs has rendered a distinct service to physicists by preparing this short account of Schrodinger's theory. Beginning with the hypotheses of Louis de Broglie, out of which the subject has developed, he traces the evolution of the idea that wave-mechanics bears to classical mechanics the same relation as wave-optics bears to ray-optics, and obtains the partial differential equation for the  $\psi$ -waves, proceeding then to its applications in spectroscopy. The style is lively and readable, the points are well made, and altogether no better introduction to the latest phase of the quantum theory can be desired. We may perhaps offer two slight criticisms • the translation of Eigenwerte by " special values " seems particularly unfortunate for those who dislike "characteristic values" or 'autovalues," the term "double numbers" may be suggested: and the mathematical treatment of the hydrogen-atom problem is greatly simplified, as Prof. Eddington pointed out some time ago in a letter to NATURE, by referring to the known properties of the  $W_{k,m}$  functions.

Local Geology: a Guide to Sources of Information on the Geology of the British Isles. By Dr A. Morley Davies. Second edition. Pp 16. (London: Thomas Murby and Co., 1927.) 1s. net.

IT is a pleasure to be given a second opportunity of directing attention to Dr. Morley Davies' extremely useful little pamphlet, partly because it is intrinsically of great educational value, and partly because the call for a second edition indicates that it is adequately serving its purpose. Our splendid series of geological maps are not nearly so well known as they should be. Dr. Davies has done the Geological Survey of Great Britain a service as well as the general public by providing this simple and interesting guide. An appendix has now been added listing new maps and leading references. One sentence is worth quoting in the hope that the Geological Survey may be encouraged to remove what is a common source of annoyance in the north of England and south of Scotland: "Unfortunately, sheets 1, 2, and 11 cover very small portions of England and much larger portions of Scotland, but they treat Scotland as a terra incognita."

## The "Palæolithic Implements" from Sligo.

HAVING regard to the apparent importance of the discovery recently announced in letters from Messrs. J. P. T. Burchell and J. Reid Moir (Nature, Aug 20 and Sept. 24, 1927), and to the publicity which the matter has received in the Press, we considered it advisable to examine the several localities indicated. This we have now done. We had no difficulty in identifying the various sites, although some inaccuracies in the descriptions suggest that these were written from memory, and not from adequate notes taken on the spot.

The western or seaward side of the promontory called Rosses Point, the site of Mr Burchell's "rock-shelter," has three projections of limestone jutting mto the sea, with areas of sand between. Mr. Burchell does not state on which of these projections his "rock-shelter" is situated, but says that it "has a south-westerly aspect." We found on the middle projection a small undercutting of the cliff, facing south-west, which might conceivably have been a fallen-in rock-shelter; it is about 100 yards to the south of the lighthouse. But in no other way does it correspond to Mr Burchell's description; there are no "fallen blocks" upon its floor. The only hollow which agrees with the description in this respect, and in dimensions, is on the southern projection; but it faces magnetic north. It is about 100 yards north of the ladies' bathing-place

Mr Burchell describes an "Early Neolithic Raised Beach," consisting of "powdered shells to a depth of one foot" as "covering what remains of the roof" of his rock-shelter. No such feature exists above the roof of either of the rock-hollows just referred to. Indeed, there is no Raised Beach of any date in the district. The only covering above both of the hollows is a layer of gravelly soil, formed by disintegration of the limestone in situ, mixed with windborne sand and occasional fragments of shells. These shells were doubtless carried up by gulls, as is still being done. They are of species now common in the bay (Mya arenaria, Solen siliqua, Ostrea edulis, Mactra solida). About twenty yards to the south of the hollow on the middle projection there is a flattened heap of fragmentary oyster-shells, possibly accumulated by human agency; these are within reach of high waves, and certainly do not form a "raised beach."

We could not detect any trace of the "boulderclay" in a hollow of which "the outer margin" of the "Raised Beach" is said to lie. Boulder-clay occurs on the northern end of the Rosses Point promontory, where, however, there are no "shelters"; and also on its southern shore, under the modern village.

The "large cave four feet high" on Coney Island lies underneath the lower of the twin beacons at the north corner of the island. We consider that its existence is clearly due to recent undermining of the massive limestone of the low cliff, by erosion of the softer underlying shales. The masonry foundation of an earlier beacon (not more than fifty years old) now overhangs the face of the cliff above the cave by about three feet, and the beacon has had to be

moved inland in consequence This shows that the process of erosion is still actively in progress

It is inconceivable that caves of this kind and in

It is inconceivable that caves of this kind and in such a situation could have persisted from Mousterian times. They are in an area that was severely glaciated by ice passing from the land out to sea. They pronouncedly jointed and bedded character of the rocks would in these circumstances give rise to excessive plucking, as is indeed evidenced by the sections below the houses of the village, where the thick masses of boulder-clay are crowded with large angular blocks of limestone. Any pre-glacial cave would thus have been obliterated. Moreover, there is abundant evidence, all along the coast, of rapid marine erosion; and any such "shelters" would have been washed away, even since Neolithic times. Similar hollows are still in process of formation indeed, it seemed to us doubtful whether the hollows under consideration were in existence at all a hundred years ago. Their floors are at such a level that they are uninhabitable, as the sea invades them at every at a higher level.

We see no reason to accept the statement that any of the countless stones littered upon the beach of Coney Island were "drifted out" of the cave. Among the mfinity of shapes which these stones present, there are some resembling choppers, scrapers, and other tools; but in no greater proportion than might be seen on any other linestone beach.

might be seen on any other limestone beach.

As to the "implements" described by Messis. Burchell and Moir, we offer the following observations. In the first place, "Mousterian implements are not, as a rule, "of impressive size." Moreover, we are at a loss to understand the meaning of the term "patination" as applied to limestone. Weathering produces a change of surface colour, but this is not putination.

Secondly, we find it impossible to understand why the hypothetical cave-dwellers made their implements of so unsatisfactory and unusual a material as linestone, when an inexhaustible supply of chert was available. Beds of chert, in many places up to six melies in thickness, form at least half of the bulk of the rocks about Rosses Point.

Thirdly, limestone, as is well known, and as we confirmed by experiments on the spot, does not break with a conchordal fracture.

Fourthly, although we found some stones which closely resembled in outline those illustrated by Mr. Burchell, careful search in all of the sites failed to reveal a single object which could be accepted as undoubtedly a human artefact of any kind whatsoever, or of any date. There was nothing in any of the sites but ordinary beach material, derived from the splintery rock of the neighbourhood.
